Package 'GPLTR'

April 10, 2022

Title Generalized Partially Linear Tree-Based Regression Model

Type Package

Version 1.3
Date 2022-04-10
Author Cyprien Mbogning <cyprien.mbogning@inserm.fr> and Wilson Toussile</cyprien.mbogning@inserm.fr>
Maintainer Cyprien Mbogning <cyprien.mbogning@gmail.com></cyprien.mbogning@gmail.com>
Description Combining a generalized linear model with an additional tree part on the same scale. A four-step procedure is proposed to fit the model and test the joint effect of the selected tree part while adjusting on confounding factors. We also proposed an ensemble procedure based on the bagging to improve prediction accuracy and computed several scores of importance for variable selection.

bag.aucoob 5

bag.aucoob

AUC on the Out Of Bag samples

Description

Compute the AUC on the OOB samples of the bagging procedure for the binomial family. The true and false positive rates are also returned and could be helpfull for plotting the ROC curves.

Usage

```
bag.aucoob(bag_pltr, xdata, Y.name)
```

Arguments

bag_pltr The output of the function bagging.pltr

xdata The learning dataset containing the dependent variable, the confounding vari-

ables and the predictors variables

Y. name The name of the binary dependent variable

Details

The thresshold values used for computing the AUC are defined when building the bagging predictor. see bagging.pltr for the convenient parameterization.

Value

A list of 4 elements

AUCOOB the AUC computed on OOB samples of the Bagging procedure

TPR the true positive rate for several thresshold values
FPR the false positive rate for several thresshold values
OOB the Out Of Bag error for each thresshold value

Note

The plot of the ROC curve is straighforward using the TPR and FPR obtained with the function bag.aucoob

Examples

##

bagging.pltr	bagging pltr models
	00 01

Description

bagging procedure to agregate several PLTR models for accurate prediction and variable selection

Usage

```
bagging.pltr(xdata, Y.name, X.names, G.names, family = "binomial",
args.rpart,epsi = 0.001, iterMax = 5, iterMin = 3, LB = FALSE,
args.parallel = list(numWorkers = 1),
Bag = 20, Pred_Data = data.frame(), verbose = TRUE, doprune = FALSE
, thresshold = seq(0, 1, by = 0.1))
```

Arguments

xdata	the learning data frame
Y.name	the name of the binary dependent variable
X.names	the names of independent variables to consider in the linear part of the glm and as offset in the tree part
G.names	the names of independent variables to consider in the tree part of the hybrid glm.
family	the glm family considered depending on the type of the dependent variable (only the binomial family works in this function for the moment) .
args.rpart	a list of options that control details of the rpart algorithm. minbucket: the minimum number of observations in any terminal <leaf> node; cp: complexity parameter (Any split that does not decrease the overall lack of fit by a factor of cp is not attempted); maxdepth: the maximum depth of any node of the final tree, with the root node counted as depth 0 See rpart.control for further details</leaf>
epsi	a treshold value to check the convergence of the algorithm
iterMax	the maximal number of iteration to consider
iterMin	the minimum number of iteration to consider

bagging.pltr 7

LB a binary indicator with values TRUE or FALSE indicating weither the loading

is balanced or not in the parallel computing. It is nevertheless useless on a

windows platform. See mclapply

args.parallel a list of two elements containing the number of workers and the type of paral-

lelization to achieve see mclapply.

Bag The number of Bagging samples to consider

Pred_Data An optional data frame to validate the bagging procedure (the test dataset)

verbose Logical; TRUE for printing progress during the computation (helpful for debug-

ging)

doprune a binary indicator with values TRUE or FALSE indicating weither the set of

trees in the bagging procedure are pruned (by a BIC procedure) or not

thresshold a vector of numerical values between 0 and 1 used as thresshold values for the

computation of the OOB error rate

Details

For the Bagging procedure, it is mendatory to set maxcompete = 0 and maxsurrogate = 0 within the rpart arguments. This will ensured the correct calculation of the importance of variables.

Value

A list with eleven elements

IND_OOB A list of length Bag containing the Out Of Bag (OOB) individuals for each PLTR

model.

EOOB The vector of OOB errors of the bagging procedure for each thresshold value.

OOB_ERRORS_PBP

A matrix with Bag columns and thresshold rows containing OOB error of each

PLTR model in the bagging sequence for each thresshold value.

OOB_ERROR_PBP A vector containing the mean of OOB_ERRORS_PBP for each thresshold value.

Tree_BAG A list of length Bag containing the bagging trees

Glm_BAG A list of length Bag containing the bagging pltr model; could be helpfull for

prediction on new features.

LOST The 0, 1 lost matrix for OOB observations at each thresshold value

TEST A value of NULL if Pred_Data is not available. A list of three elements oth-

erwise: PRED_ERROR: the estimated error of the Bagging procedure on the test sample for each thresshold value; PRED_IND: A list of length the length of the thresshold vector, each element containing a matrix with the prediction of the testing data individuals using each PLTR model of the bagging sequence (column by column); FINAL_PRED_IND: A list containing the final prediction of each individual of the testing data by the bagging procedure (the modal prediction)

for each thresshold value.

Var_IMP A numeric vector containing the relative variable importance of the bagging

procedure

Timediff The execution time of the bagging procedure

CUT The thresshold value used inside the bagging procedure

8 best.tree.BIC.AIC

Examples

best.tree.BIC.AIC

Prunning the Maximal tree

Description

this function is set to prune back the maximal tree by using the BIC or the AIC criterion.

Usage

best.tree.BIC.AIC 9

Arguments

ree to prune
į

xdata the dataset used to build the tree
Y. name the name of the dependent variable

X. names the names of independent confounding variables to consider in the linear part of

the glm

family the glm family considered depending on the type of the dependent variable.

verbose Logical; TRUE for printing progress during the computation (helpful for debug-

ging)

Value

a list of four elements:

best_index The size of the selected trees by BIC and AIC

tree The selected trees by BIC and AIC

fit_glm The fitted pltr models selected with BIC, and AIC
Timediff The execution time of the selection procedure

Author(s)

Cyprien Mbogning and Wilson Toussile

## End(Not run)
```

 $best.tree.bootstrap \hspace{0.5cm} \textit{parametric bootstrap on a pltr model}$

Description

a parametric bootstrap procedure to select and test at the same time the selected tree

best.tree.bootstrap 11

Usage

```
best.tree.bootstrap(xtree, xdata, Y.name, X.names, G.names, B = 10, BB = 10,
args.rpart = list(cp = 0, minbucket = 20, maxdepth = 10), epsi = 0.001,
iterMax = 5, iterMin = 3, family = "binomial", LEVEL = 0.05, LB = FALSE,
args.parallel = list(numWorkers = 1), verbose = TRUE)
```

Arguments

xtree the maximal tree obtained by the function pltr.glm

xdata the data frame used to build xtree
Y.name the name of the dependent variable

X. names the names of independent variables to consider in the linear part of the glmG. names the names of independent variables to consider in the tree part of the hybrid glm.

B the size of the bootstrap sample

BB the size of the bootstrap sample to compute the adjusted p-value

args.rpart a list of options that control details of the rpart algorithm. minbucket: the

minimum number of observations in any terminal <leaf> node; cp: complexity parameter (Any split that does not decrease the overall lack of fit by a factor of cp is not attempted); maxdepth: the maximum depth of any node of the final tree, with the root node counted as depth 0. ... See rpart.control for further

details

epsi a treshold value to check the convergence of the algorithm

iterMax the maximal number of iteration to consider iterMin the minimum number of iteration to consider

family the glm family considered depending on the type of the dependent variable.

LEVEL the level of the test

LB a binary indicator with values TRUE or FALSE indicating weither the loading is

balanced or not in the parallel computing. It is useless on a windows platform.

args.parallel parameters of the parallelization. See mclapply for more details

verbose Logical; TRUE for printing progress during the computation (helpful for debug-

ging)

Value

a list with six elements

selected model

a list with the fit of the selected pltr model fit_glm, the selected tree tree, the p-value of the selected tree p.value, the ajusted p-value of the selected tree adj_p.value and an indicator Tree_Selected to assess wether the test is

significant or not.

fit_glm the fitted pltr model under the null hypothesis if the test is not significant

Timediff The execution time of the parametric bootstrap procedure

comp_p_values The P-values of the competing trees

Badj The number of samples used in the inner level of the procedure

The number of samples used in the outer level of the procedure

best.tree.CV

Prunning the Maximal tree

Description

this function is set to prune back the maximal tree by using a K-fold cross-validation procedure.

Usage

```
best.tree.CV(xtree, xdata, Y.name, X.names, G.names, family = "binomial",
args.rpart = list(cp = 0, minbucket = 20, maxdepth = 10), epsi = 0.001,
iterMax = 5, iterMin = 3, ncv = 10, verbose = TRUE)
```

best.tree.CV 13

Arguments

args.rpart

xtree a tree to prune

xdata the dataset used to build the tree the name of the dependent variable Y.name

X.names the names of independent variables to consider in the linear part of the glm G.names the names of independent variables to consider in the tree part of the hybrid glm. family the glm family considered depending on the type of the dependent variable.

a list of options that control details of the rpart algorithm. minbucket: the

minimum number of observations in any terminal <leaf> node; cp: complexity parameter (Any split that does not decrease the overall lack of fit by a factor of cp is not attempted); maxdepth: the maximum depth of any node of the final tree, with the root node counted as depth 0. ... See rpart.control for further

details

a treshold value to check the convergence of the algorithm epsi

the maximal number of iteration to consider iterMax iterMin the minimum number of iteration to consider

The number of folds to consider for the cross-validation ncv

verbose Logical; TRUE for printing progress during the computation (helpful for debug-

ging)

Value

a list of five elements:

The size of the selected tree by the cross-validation procedure best_index

The selected tree by CV tree

fit_glm The fitted gpltr models selected with CV

CV_ERRORS A list of two elements containing the cross-validation error of the selected tree

by the CV procedure and a vector of cross-validation errors of all the competing

models

Timediff The execution time of the Cross-Validation procedure

best.tree.permute

permutation test on a pltr model

Description

a unified permutation test procedure to select and test at the same time the selected tree

Usage

```
best.tree.permute(xtree, xdata, Y.name, X.names, G.names, B = 10,
   args.rpart = list(cp = 0, minbucket = 20, maxdepth = 10), epsi = 0.001,
   iterMax = 5, iterMin = 3, family = "binomial", LEVEL = 0.05,
   LB = FALSE, args.parallel = list(numWorkers = 1, type = "PSOCK"), verbose = TRUE)
```

Arguments

xtree the maximal tree obtained by the function pltr.glm xdata the data frame used to build xtree

best.tree.permute 15

Y. name the name of the dependent variable

X. names the names of independent variables to consider in the linear part of the glm. For

this function, only a binary variable is supported.

G. names the names of independent variables to consider in the tree part of the hybrid glm.

B the size of the bootstrap sample

args.rpart a list of options that control details of the rpart algorithm. minbucket: the

minimum number of observations in any terminal <leaf> node; cp: complexity parameter (Any split that does not decrease the overall lack of fit by a factor of cp is not attempted); maxdepth: the maximum depth of any node of the final tree, with the root node counted as depth 0. ... See rpart.control for further

details

epsi a treshold value to check the convergence of the algorithm

iterMax the maximal number of iteration to consider iterMin the minimum number of iteration to consider

family the binomial family.

LEVEL the level of the test

LB a binary indicator with values TRUE or FALSE indicating weither the loading is

balanced or not in the parallel computing. It is useless on a windows platform.

args.parallel parameters of the parallelization. See mclapply for more details.

verbose Logical; TRUE for printing progress during the computation (helpful for debug-

ging)

Value

a list with six elements:

p.val_selected

the adjusted p-value of the selected tree

selected_model

a list with the fit of the selected pltr model fit_glm, the selected tree tree and the p-value of the selected tree without adjusting for multiple comparisons

p.value

fit_glm the fitted pltr model under the null hypothesis if the test is not significant

Timediff The execution time of the permutation test procedure

comp_p_values The P-values of the competing trees

Badj The number of samples used inside the procedure

```

burn

burn dataset

Description

The burn data frame has 154 rows and 17 columns.

Usage

```
data(burn)
```

Format

A data frame with 154 observations on the following 17 variables.

Obs Observation number

- Z1 Treatment: 0-routine bathing 1-Body cleansing
- Z2 Gender (0=male 1=female)
- Z3 Race: 0=nonwhite 1=white

data_pltr 17

- Z4 Percentage of total surface area burned
- Z5 Burn site indicator: head 1=yes, 0=no
- Z6 Burn site indicator: buttock 1=yes, 0=no
- Z7 Burn site indicator: trunk 1=yes, 0=no
- Z8 Burn site indicator: upper leg 1=yes, 0=no
- Z9 Burn site indicator: lower leg 1=yes, 0=no
- Z10 Burn site indicator: respiratory tract 1=yes, 0=no
- Z11 Type of burn: 1=chemical, 2=scald, 3=electric, 4=flame
- T1 Time to excision or on study time
- D1 Excision indicator: 1=yes 0=no
- T2 Time to prophylactic antibiotic treatment or on study time
- D2 Prophylactic antibiotic treatment: 1=yes 0=no
- T3 Time to straphylocous aureaus infection or on study time
- D3 Straphylocous aureaus infection: 1=yes 0=no

```

data_pltr

gpltr data example

Description

A data frame to test the functions of the package

Usage

```
data(data_pltr)
```

18 nested.trees

Format

A data frame with 3000 observations on the following 16 variables.

```
G1 a numeric vector
```

- G2 a factor with levels 0 1
- G3 a factor with levels 0 1
- G4 a factor with levels 0 1
- G5 a factor with levels 0 1
- G6 a binary numeric vector
- G7 a binary numeric vector
- G8 a binary numeric vector
- G9 a binary numeric vector
- G10 a binary numeric vector
- G11 a binary numeric vector
- G12 a binary numeric vector
- G13 a binary numeric vector
- G14 a binary numeric vector
- G15 a binary numeric vector
- Y a binary numeric vector

Details

The numeric variable G1 is considered as offset in the simulated PLTR model; the variables G2,...,G5 are used to simulate the tree part, while G6,...,G15 are noise variables.

Examples

```
data(data_pltr)
## maybe str(data_pltr) ...
```

nested.trees

compute the nested trees

Description

Compute a sequence of nested competing trees for the prunning step

Usage

```
nested.trees(xtree, xdata, Y.name, X.names, MaxTreeSize = NULL,
family = "binomial", verbose = TRUE)
```

nested.trees 19

Arguments

xtree a tree inheriting to the rpart method xdata the dataset used to build the tree

Y. name the name of the dependent variable in the tree model

X. names the names of independent variables considered as offset in the tree model

MaxTreeSize The maximal size of the competing trees

family the glm family considered depending on the type of the dependent variable.

verbose Logical; TRUE for printing progress during the computation (helpful for debug-

ging)

Value

a list with 4 elements:

leaves a list of leaves of the competing trees to consider for the optimal tree

null_deviance the deviance of the null model (linear part of the glm)
deviances a vector of deviances of the competing PLTR models

diff_deviances a vector of the deviance differencies between the competing PLTR models and

the null model

Author(s)

Cyprien Mbogning and Wilson Toussile

p.val.tree

p.val.tree	Compute the p-value	

Description

Test weither the selected tree by either BIC, AIC or CV procedure is significantly associated to the dependent variable or not, while adjusting for a confounding effect.

Usage

```
p.val.tree(xtree, xdata, Y.name, X.names, G.names, B = 10, args.rpart =
list(minbucket = 40, maxdepth = 10, cp = 0), epsi = 0.001, iterMax = 5,
iterMin = 3, family = "binomial", LB = FALSE,
args.parallel = list(numWorkers = 1), index = 4, verbose = TRUE)
```

Arguments

xtree	the maximal tree obtained by the function pltr.glm
	, , ,
xdata	the data frame used to build xtree
Y.name	the name of the dependent variable
X.names	the names of independent confounding variables to consider in the linear part of the ${\tt glm}$
G.names	the names of independent variables to consider in the tree part of the hybrid glm.
В	the resampling size of the deviance difference
args.rpart	a list of options that control details of the rpart algorithm. minbucket: the minimum number of observations in any terminal <leaf> node; cp: complexity parameter (Any split that does not decrease the overall lack of fit by a factor of cp is not attempted); maxdepth: the maximum depth of any node of the final tree, with the root node counted as depth 0 See rpart.control for further details</leaf>
epsi	a treshold value to check the convergence of the algorithm
iterMax	the maximal number of iteration to consider
iterMin	the minimum number of iteration to consider
family	the glm family considered depending on the type of the dependent variable.
LB	a binary indicator with values TRUE or FALSE indicating weither the loading are balanced or not in the parallel computing
args.parallel	parameters of the parallelization. See mclapply for more details.
index	the size of the selected tree (by the functions best.tree.BIC.AIC or best.tree.CV) using one of the proposed criteria
verbose	Logical; TRUE for printing progress during the computation (helpful for debugging)

p.val.tree 21

Value

A list of three elements:

p. value The P-value of the selected tree

Timediff The execution time of the test procedure

Badj The number of samples used inside the the procedure

Author(s)

Cyprien Mbogning

22 pltr.glm

pltr.glm

Partially tree-based regression model function

Description

The pltr.glm function is designed to fit an hybrid glm model with an additive tree part on a glm scale

Usage

```
pltr.glm(data, Y.name, X.names, G.names, family = "binomial",
    args.rpart = list(cp = 0, minbucket = 20, maxdepth = 10),
    epsi = 0.001, iterMax = 5, iterMin = 3, verbose = TRUE)
```

Arguments

data	a data frame containing the variables in the model
Y.name	the name of the dependent variable
X.names	the names of independent variables to consider in the linear part of the glm
G.names	the names of independent variables to consider in the tree part of the hybrid glm.
family	the glm family considered depending on the type of the dependent variable.
args.rpart	a list of options that control details of the rpart algorithm. minbucket: the minimum number of observations in any terminal <leaf> node; cp: complexity parameter (Any split that does not decrease the overall lack of fit by a factor of cp is not attempted); maxdepth: the maximum depth of any node of the final tree, with the root node counted as depth 0 See rpart.control for further details</leaf>
epsi	a treshold value to check the convergence of the algorithm
iterMax	the maximal number of iteration to consider
iterMin	the minimum number of iteration to consider
verbose	Logical; TRUE for printing progress during the computation (helpful for debugging)

Details

The pltr.glm function use an itterative procedure to fit the linear part of the glm and the tree part. The tree obtained at the convergence of the procedure is a maximal tree which overfits the data. It's then mandatory to prunned back this tree by using one of the proposed criteria (BIC, AIC and CV).

pltr.glm 23

Value

A list with four elements:

fit the glm fitted on the confounding factors at the end of the iterative algorithm

tree the maximal tree obtained at the end of the algorithm

nber_iter the number of iterations used by the algorithm
Timediff The execution time of the iterative procedure

Note

The tree obtained at the end of these itterative procedure usually overfits the data. It's therefore mendatory to use either best.tree.BIC.AIC or best.tree.CV to prunne back the tree.

rpart

24 predict_bagg.pltr

predict_bagg.pltr

prediction on new features

Description

Prediction on new features using a set of bagging pltr models

Usage

Arguments

bag_pltr

thresshold

Y. name the name of the binary dependent variable

a data frame in which to look for predictors and the dependant variable.

type the type of prediction required. type = "response" is the default; It gives the predicted probabilities. At this stage of the package, only this type is take into account. Other types such as "link" and "terms" are useless.

the bagging result obtained with the function bagging.pltr

a vector of cutoff values for binary prediction. Could be helpfull for computing

the AUC on the test sample.

predict_bagg.pltr 25

Value

A list with 8 elements

FINAL PRED IND1

A list of size the length of the thresshold vector, containing the final prediction of each individual of the testing data by the bagging procedure using the majority rule (the modal prediction).

FINAL PRED IND2

A list of size the length of the thresshold vector, containing the final prediction of each individual of the testing data by the bagging procedure using the mean estimated probability.

PRED_ERROR1 A vector of estimated errors of the Bagging procedure on the test sample for

each thresshold value using FINAL_PRED_IND1.

PRED_ERROR2 A vector of estimated errors of the Bagging procedure on the test sample for

each thresshold value using FINAL_PRED_IND2.

CONF1 A list of confusion matrix using FINAL_PRED_IND1
CONF2 A list of confusion matrix using FINAL_PRED_IND2

PRED_ERRORS_PBP

A list of size the length of the thresshold vector. Each element representing the prediction error obtained via each predictor in the bagging sequence for each thresshold value

PRED_ERROR_PBP A vector containing the mean of PRED_ERRORS_PBP for each thresshold value

family <- "binomial"
Y.name <- "D2"</pre>
```

26 predict_pltr

predict_pltr

prediction

Description

prediction on new features using a pltr tree and the name of the confounding variable

Usage

Arguments

xtree	a tree obtained with the pltr procedure
xdata	the dataframe used to learn the pltr model
Y.name	the name of the main variable

X.names the names of the confounding variables

newdata the new data with all the predictors and the dependent variable

type the type of prediction family the glm family considered

thresshold the thresshold value to consider for binary prediction. It could be a vector, help-

ing to compute the AUC

tree2glm 27

Value

A list of two element

predict_glm the predicted vector, depending on the family used. For the binomial family with

a vector of thresshold, a matrix with each column corresponding to a thresshold

value

ERR_PRED either the prediction error of the pltr procedure on the test set or a vector of

prediction error when the family is binomial with a vector of thresshold values

##

tree2glm	tree to GLM

Description

fit the PLTR model for a given tree. The tree is coerced into dummy covariates.

Usage

```
tree2glm(xtree, xdata, Y.name, X.names, family = "binomial")
```

Arguments

xtree	a tree inherits from the rpart method

xdata a data frame containing the variables in the model

Y. name the name of the dependent variable

X. names the names of independent variables to consider in the linear part of the glm family the glm family considered depending on the type of the dependent variable.

28 tree2indicators

Value

```
the pltr fitted model (fit)
```

Author(s)

Cyprien Mbogning and Wilson Toussile

Examples

```
## Not run:
##load the data set
data(data_pltr)
## set the parameters
args.rpart <- list(minbucket = 40, cp = 0)</pre>
family <- "binomial"</pre>
Y.name <- "Y"
X.names <- "G1"
G.names <- paste("G", 2:15, sep="")</pre>
## build a maximal tree
fit_pltr <- pltr.glm(data_pltr, Y.name, X.names, G.names, args.rpart = args.rpart,</pre>
                      family = family,iterMax = 5, iterMin = 3)
## Coerce a tree into a glm model using the confonding factor
fit_glm <- tree2glm(fit_pltr$tree, data_pltr, Y.name, X.names,</pre>
                     family = family)
summary(fit_glm)
## End(Not run)
```

tree2indicators

From a tree to indicators (or dummy variables)

Description

Coerces a given tree structure to binary covariates.

Usage

```
tree2indicators(fit)
```

Arguments

fit

a tree structure inheriting to the rpart method

VIMPBAG 29

Value

a list of indicators

Author(s)

Cyprien Mbogning and Wilson Toussile

Examples

VIMPBAG

score of importance for variables

Description

Several variable importance scores are computed: the deviance importance score (DIS), the permutation importance score (PIS), the depth deviance importance score (DDIS), the minimal depth importance score (MinDepth) and the occurrence score (OCCUR).

Usage

```
VIMPBAG(BAGGRES, data, Y.name)
```

30 VIMPBAG

Arguments

BAGGRES The output of the bagging procedure (bagging.pltr)

data The learning dataframe used within the bagging procedure

Y. name The name of the binary dependant variable used in the bagging procedure

Details

several choices for variable selection using the bagging procedure are proposed. A discussion about the scores of importance PIS, DIS, and DDIS is available in Mbogning et al. 2015

Value

A list with 9 elements

PIS A list of length the length of the thresshold value used in the bagging procedure,

containing the permutation importance score displayed in decreasing order for

each thresshold value

StdPIS The standard error of the PIS

OCCUR The occurrence number for each variable in the bagging sequence displayed in

decreasing order

DIS The deviance importance score displayed in decreasing order

DDIS The depth deviance importance score displayed in decreasing order

MinDepth The minimal depth score for each variable, displayed in increasing order

dimtrees A vector containing the dimensions of trees within the baging sequence

E00B A vector containing the OOB error of the bagging procedure for each thresshold

value

Bagfinal The number of Bagging iterations used
