Package 'Rfast2'

March 23, 2022

Type Package
Title A Collection of Efficient and Extremely Fast R Functions II
Version 0.1.3
Date 2022-03-22
Author Manos Papadakis, Michail Tsagris, Stefanos Fafalios and Marios Dimitriadis.
Maintainer Manos Papadakis <rfastofficial@gmail.com></rfastofficial@gmail.com>
Depends R (>= 3.5.0), Rcpp (>= 0.12.3)
LinkingTo Rcpp (>= 0.12.3), RcppArmadillo
Imports Rfast, RANN
SystemRequirements C++11
<pre>BugReports https://github.com/RfastOfficial/Rfast2/issues</pre>
<pre>URL https://github.com/RfastOfficial/Rfast2</pre>
Description A collection of fast statistical and utility functions for data analysis. Functions for regression, maximum likelihood, column-wise statistics and many more have been included. C++ has been utilized to speed up the functions.
License GPL (>= 2.0)
NeedsCompilation yes
Repository CRAN
Date/Publication 2022-03-23 07:50:24 UTC

Bootstrap James and Hotelling test for 2 independent sample mean vectors	. 13
Bootstrap Student's t-test for 2 independent samples	
Censored Weibull regression model	
Check if a matrix is Lower or Upper triangular	
Check whether a square matrix is skew-symmetric	
Circurlar correlations between two circular variables	
Column and row-wise jackknife sample means	
Column-wise means and variances	. 21
Column-wise MLE of some univariate distributions	
Column-wise MLE of the angular Gaussian distribution	. 23
Column-wise pooled variances across groups	
Column-wise summary statistics with grouping variables	
Conditional least-squares estimate for Poisson INAR(1) models	
Constrained least squares	
Contour plots of some bivariate distributions	
Correlation significance testing using Fisher's z-transformation	
Covariance between a variable and a matrix of variables	
Cross-validation for the k-NN algorithm for really lage scale data	
Cross-validation for the multinomial regression	
Cross-validation for the naive Bayes classifiers	
Cross-validation for the regularised maximum likelihood linear discriminant analysis .	
Diagonal values of the Hat matrix	
Distance between two covariance matrices	
Distance correlation matrix	. 39
Empirical entropy	. 40
Fisher's linear discriminant analysis	
Fixed effects regression	
Fixed intercepts Poisson regression	
Forward Backward Early Dropping selection regression	
Fractional polynomial regression with one independent variable	
Gamma regression with a log-link	
GEE Gaussian regression	. 49
Gumbel regression	. 50
Hellinger distance based regression for count data	
Hellinger distance based univariate regression for proportions	. 53
Heteroscedastic linear models for large scale data	
Hurdle-Poisson regression	
Hypothesis tests for equality of a covariance matrix	. 56
Hypothesis tests for equality of multiple covariance matrices	
Intersect	
Item difficulty and discrimination	
Jackknife sample mean	
Kaplan-Meier estimate of a survival function	
Linear regression with clustered data	
Mahalanobis depth	
Many 2 sample student's t-tests	
Many approximate simple logistic regressions	
Many binary classification metrics	

Many Gamma regressions
Many metrics for a continuous response variable
Many negative binomial regressions
Many score based regressions with muliple response variables and a single predictor
variable
Many score based zero inflated Poisson regressions
Many simple quantile regressions using logistic regressions
Many simple Weibull regressions
Many Welch tests
Max-Min Parents and Children variable selection algorithm for continuous responses
e
•
Merge 2 sorted vectors in 1 sorted vector
MLE of continuous univariate distributions defined on the positive line
MLE of distributions defined for proportions
MLE of some circular distributions with multiple samples
MLE of some truncated distributions
MLE of the Cauchy and generalised normal distributions with zero location $\dots \dots 89$
MLE of the censored Weibull distribution
MLE of the gamma-Poisson distribution
MLE of the left censored Poisson distribution
MLE of the Purkayastha distribution
MLE of the zero inflated Gamma and Weibull distributions
Monte Carlo integration with a normal distribution
Moran's I measure of spatial autocorrelation
Multinomial regression
Naive Bayes classifier for binary (Bernoulli) data
Naive Bayes classifiers
Naive Bayes classifiers for circular data
Negative binomial regression
Non linear least squares regression for percentages or proportions
One sample bootstrap t-test for a vector
Orthogonal matching pursuit variable selection
Parametric bootstrap for linear regression model
Permutation t-test for 2 independent samples
Prediction with naive Bayes classifier for binary (Bernoulli) data
Prediction with some naive Bayes classifiers
Prediction with some naive Bayes classifiers for circular data
Principal component analysis
Principal components regression
Random effects meta analysis
Random integer values simulation
Random values generation from a Be(a, 1) distribution
Random values simulation from the uniform distribution
Regularised maximum likelihood linear discriminant analysis
Repeated measures ANOVA (univariate data) using Hotelling's T2 test
Sample quantiles and col/row wise quantiles
Scaled logistic regression

4 Rfast2-package

	Score test for overdispersion in Poisson regression	123
	Single terms deletion hypothesis testing in a linear regression model	124
	Skeleton of the FEDHC algorithm	126
	Skeleton of the MMHC algorithm	127
	Split the matrix in lower, upper triangular and diagonal	129
	The k-NN algorithm for really lage scale data	130
	Tobit regression	131
	Trimmed mean	133
	Variable selection using the PC-simple algorithm	134
	Wald confidence interval for the ratio of two Poisson variables	135
	Walter's confidence interval for the ratio of two binomial variables (and the relative risk)	136
	Zero inflated Gamma regression	137
	Zero truncated Poisson regression	139
Index		141
Rfast	t2-package Really fast R functions	

Description

A collection of Rfast2 functions for data analysis. Note 1: The vast majority of the functions accept matrices only, not data.frames. Note 2: Do not have matrices or vectors with have missing data (i.e NAs). We do no check about them and C++ internally transforms them into zeros (0), so you may get wrong results. Note 3: In general, make sure you give the correct input, in order to get the correct output. We do no checks and this is one of the many reasons we are fast.

Details

Package: Rfast2
Type: Package
Version: 0.1.3
Date: 2022-03-22
License: GPL-2

Manos Papadakis <rfastofficial@gmail.com>

Author(s)

Manos Papadakis <papadakm95@gmail.com>, Michail Tsagris <mtsagris@uoc.gr>, Stefanos Fafalios <stefanosfafalios@gmail.com>, Marios Dimitriadis <kmdimitriadis@gmail.com>.

Add many single terms to a model

Add many single terms to a model

Description

Add many single terms to a model.

Usage

```
add.term(y, xinc, xout, devi_0, type = "logistic", logged = FALSE,
tol = 1e-07, maxiters = 100, parallel = FALSE)
```

Arguments

У		The response variable. It must be a numerical vector.
Х	inc	The already included indendent variable(s).
Х	out	The independent variables whose conditional association with the response is to be calculated.
d	levi_0	The deviance for Poisson, logistic, qpoisson, qlogistic and normlog regression or the log-likelihood for the Weibull, spml and multinomial regressions. See the example to understand better.
t	ype	The type of regression, "poisson", "logistic", "qpoisson" (quasi Poisson), "qlogistic" (quasi logistic) "normlog" (Gaussian regression with log-link) "weibull", "spml" and "multinom".
1	ogged	Should the logarithm of the p-value be returned? TRUE or FALSE.
t	ol	The tolerance value to terminate the Newton-Raphson algorithm when fitting the regression models.
m	axiters	The maximum number of iterations the Newton-Raphson algorithm will perform.
р	arallel	Should the computations take place in parallel? TRUE or FALSE.

Details

The function is similar to the built-in function add1. You have already fitted a regression model with some independent variables (xinc). You then add each of the xout variables and test their significance.

Value

A matrix with two columns. The test statistic and its associated (logged) p-value.

x <- matrix( rnorm(200 * 10), ncol = 10)
y <- rpois(200, 10)
devi_0 <- deviance( glm(y ~ x[, 1:2], poisson) )
a <- add.term(y, xinc = x[,1:2], xout = x[, 3:10], devi_0 = devi_0, type= "poisson")

y <- rbinom(200, 1, 0.5)
devi_0 <- deviance( glm(y ~ x[, 1:2], binomial) )
a <- add.term(y, xinc = x[,1:2], xout = x[, 3:10], devi_0 = devi_0, type= "logistic")

y <- rbinom(200, 2, 0.5)
devi_0 <- Rfast::multinom.reg(y, x[, 1:2])$loglik
a <- add.term(y, xinc = x[,1:2], xout = x[, 3:10], devi_0 = devi_0, type= "multinom")

y <- rgamma(200, 3, 1)
devi_0 <- Rfast::weib.reg(y, x[, 1:2])$loglik
a <- add.term(y, xinc = x[,1:2], xout = x[, 3:10], devi_0 = devi_0, type= "weibull")</pre>
```

Angular Gaussian random values simulation

Angular Gaussian random values simulation

Description

Angular Gaussian random values simulation.

Usage

```
riag(n, mu)
```

Arguments

n The sample size, a numerical value.

mu The mean vector in \mathbb{R}^d .

Anova for circular data 7

Details

The algorithm uses univariate normal random values and with some mean. The vectors are then scaled to have unit length.

Value

A matrix with the simulated data.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```

Anova for circular data

Analysis of variance for circular data

Description

Analysis of variance for circular data.

Usage

```
hcf.circaov(u, ina)
lr.circaov(u, ina)
het.circaov(u, ina)
embed.circaov(u, ina)
```

8 Anova for circular data

Arguments

u A numeric vector containing the data that are expressed in rads.

ina A numerical or factor variable indicating the group of each value.

Details

The high concentration (hcf.circaov), log-likelihood ratio (lr.circaov), embedding approach (embed.circaov) or the non equal concentration parameters approach (het.circaov) is used.

Value

A vector including:

test The value of the test statistic.

p-value The p-value of the test.

kapa The concentration parameter based on all the data. If the het.circaov is used this

argument is not returned.

```

Backward selection with the F test or the partial correlation coefficient backward selection with the F test or the partial correlation coefficient

Description

backward selection with the F test or the partial correlation coefficient.

Usage

```
lm.bsreg(y, x, alpha = 0.05, type = "F")
```

Arguments

У	The dependent variable, a numerical vector with numbers.
X	A numerical matrix with the indendent variables. We add, internally, the first column of ones.
alpha	If you want to perform the usual F (or t) test set this equal to "F". For the test based on the partial correlation set this equal to "cor".
type	The type of backward selection to be used, "F" stands for F-test, where "cor" stands for partial correlation.

Details

It performs backward selection with the F test or the partial correlation coefficient. For the linear regression model, the Wald test is equivalent to the partial F test. So, instead of performing many regression models with single term deletions we perform one regression model with all variables and compute their Wald test effectively. Note, that this is true, only if the design matrix "x" contains the vectors of ones and in our case this must be, strictly, the first column. The second option is to compute the p-value of the partial correlation.

Value

A matrix with two columns. The removed variables and their associated pvalue.

lm.bsreg(y, x)</pre>
```

Benchmark - Measure time

Benchmark - Measure time

Description

Benchmark - Measure time.

Usage

```
benchmark(...,times,envir=parent.frame(),order=NULL)
## S3 method for class 'benchmark'
print(x,...)
```

Arguments

Expressions to the benchmark function.
 Object of class "benchmark" to print.
 Number of time to measure execution time of the expression.
 envir
 Environment to evaluate the expressions.

order An integer vector to execute the epxressions with this order, otherwise the exe-

cution order is random.

Details

For measuring time we have used C++'s new library "chrono".

Value

The execution time for each expression.

```

BIC of many simple univariate regressions

BIC of many simple univariate regressions.

Description

BIC of many simple univariate regressions.

Usage

```
bic.regs(y, x, family = "normal")
```

Arguments

y The dependent variable, a numerical vector.

x A matrix with the indendent variables.

family The family of the regression models. "normal", "binomial", "poisson", "multi-

nomial", "normlog" (Gaussian regression with log link), "spmpl" (SPML regres-

sion) or "weibull" for Weibull regression.

Details

Many simple univariate regressions are fitted and the BIC of every model is computed.

Value

A vector with the BIC of each regression model.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

12 Binomial regression

Examples

```
y <- rbinom(100, 1, 0.6)
x <- matrix( rnorm(100 * 50), ncol = 50 )
bic.regs(y, x, "binomial")</pre>
```

Binomial regression

Binomial regression

Description

Binomial regression.

Usage

```
binom.reg(y, ni, x, full = FALSE, tol = 1e-07, maxiters = 100)
```

Arguments

У	The dependent variable; a numerical vector with integer values, 0, 1, 2, The successes.
ni	A vector with integer values, greater than or equal to y. The trials.
X	A matrix with the data, where the rows denote the samples (and the two groups) and the columns are the variables. This can be a matrix or a data.frame (with factors).
full	If this is FALSE, the coefficients and the deviance will be returned only. If this is TRUE, more information is returned.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
maxiters	The max number of iterations that can take place in each regression.

Details

The difference from logistic regression is that in the binomial regression the binomial distribution is used and not the Bernoulli.

Value

When full is FALSE a list including:

be The regression coefficients.
devi The deviance of the model.

When full is TRUE a list including:

info The regression coefficients, their standard error, their Wald test statistic and their

p-value.

devi The deviance.

x <- NULL
```

Bootstrap James and Hotelling test for 2 independent sample mean vectors

Bootstrap James and Hotelling test for 2 independent sample mean vectors

Description

Bootstrap James and Hotelling test for 2 independent sample mean vectors.

Usage

```
boot.james(y1, y2, R = 999)
boot.hotel2(y1, y2, R = 999)
```

Arguments

y1 A numerical matrix with the data of the one sample.

y2 A numerical matrix with the data of the other sample.

R The number of bootstrap samples to use.

Details

We bootstrap the 2-samples James (does not assume equal covariance matrics) and Hotelling test (assumes equal covariance matrics). The difference is that the Hotelling test statistic assumes equality of the covariance matrices, which if violated leads to inlfated type I errors. Bootstrap calibration though takes care of this issue. As for the bootstrap calibration, instead of sampling B times from each sample, we sample sqrtB from each of them and then take all pairs. Each bootstrap sample is independent of each other, hence there is no violation of the theory (Chatzipantsiou et al., 2019).

Value

The bootstrap p-value.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```

```
Bootstrap Student's t-test for 2 independent samples

Bootstrap Student's t-test for 2 independent samples
```

Description

Bootstrap Student's t-test for 2 independent samples.

Usage

```
boot.student2(x, y, B = 999)
```

Arguments

- x A numerical vector with the data.
- y A numerical vector with the data.
- B The number of bootstrap samples to use.

Details

We bootstrap Student's (Gosset's) t-test statistic and not the Welch t-test statistic. For the latter case see the "boot.ttest2" function in Rfast. The difference is that Gosset's test statistic assumes equaility of the variances, which if violated leads to inlfated type I errors. Bootstrap calibration though takes care of this issue. As for the bootstrap calibration, instead of sampling B times from each sample, we sample sqrtB from each of them and then take all pairs. Each bootstrap sample is independent of each other, hence there is no violation of the theory (Chatzipantsiou et al., 2019).

Value

A vector with the test statistic and the bootstrap p-value.

Censored Weibull regression model

Censored Weibull regression model

Description

Censored Weibull regression model.

Usage

```
censweib.reg(y, x, di, tol = 1e-07, maxiters = 100)
```

Arguments

У	The dependent variable; a numerical vector with strictly positive data, i.e. greater than zero.
X	A matrix with the data, where the rows denote the samples (and the two groups) and the columns are the variables. This can be a matrix or a data.frame (with factors).
di	A vector with 1s and 0s indicating the censored value. The value of 1 means uncesored value, whereas the value of 0 means censored value.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
maxiters	The max number of iterations that can take place in each regression.

Details

The function is written in C++ and this is why it is very fast. No standard errors are returned as they are not corectly estimated. We focused on speed.

Value

When full is FALSE a list including:

iters The iterations required by the Newton-Raphson.

loglik The log-likelihood of the model.

shape The shape parameter of the Weibull regression.

be The regression coefficients.

Check if a matrix is Lower or Upper triangular

Check if a matrix is Lower or Upper triangular
```

Description

Lower/upper triangular matrix.

Usage

```
is.lower.tri(x, diag = FALSE)
is.upper.tri(x, diag = FALSE)
```

Arguments

x A matrix with data.diag A logical value include the diagonal to the result.

Value

Check if a matrix is lower or upper triangular. You can also include diagonal to the check.

Check whether a square matrix is skew-symmetric

Check whether a square matrix is skew-symmetric

Description

Check whether a square matrix is skew-symmetric.

Usage

```
is.skew.symmetric(x)
```

Arguments

Х

A square matrix with data.

Details

Instead of going through the whole matrix, the function will stop if the first disagreement is met.

Value

A boolean value, TRUE of FALSE.

Circurlar correlations between two circular variables

Circurlar correlations between two circular variables

Description

Circurlar correlations between two circular variables.

Usage

```
circ.cor1(theta, phi, pvalue = FALSE)
circ.cors1(theta, phi, pvalue = FALSE)
```

Arguments

theta The first cirular variable expressed in radians, not degrees.

phi The other cirular variable. In the case of "circ.cors1" this is a matrix with many

circular variables. In either case, the values must be in radians, not degrees.

pvalue If you want the p-value of the zero correlation hypothesis testing set this to

TRUE, otherwise leave it FALSE.

Details

Correlation for circular variables using the cosinus and sinus formula of Jammaladaka and Sen-Gupta (1988).

Value

If you set pvalue = TRUE, then for the "circ.cor1" a vector with two values, the correlation and its associated p-value, otherwise the correlation only. For the "circ.cors1", either a vector with the correlations only or a matrix with two columns, the correlation and the p-values.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

circ.cors1(y, x, TRUE)</pre>
```

Column and row-wise jackknife sample means

Column and row-wise jackknife sample means

Description

Column and row-wise jackknife sample means.

Usage

```
coljack.means(x)
rowjack.means(x)
```

Arguments

Χ

A numerical matrix with data.

Details

An efficient implementation of the jackknife mean is provided.

Value

A vector with the jackknife sample means.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

Column-wise means and variances

Column-wise means and variances of a matrix

Description

Column-wise means and variances of a matrix.

Usage

```
colmeansvars(x, std = FALSE, parallel = FALSE)
```

Arguments

x A matrix with the data.

std A boolean variable specyfying whether you want the variances (FALSE) or the

standard deviations (TRUE) of each column.

parallel A boolean value for parallel version.

Details

This function cacluates the column-wise means and variances (or standard deviations).

Value

A matrix with two rows. The first contains the means and the second contains the variances (or standard deviations).

Author(s)

Michail Tsagris.

```

Column-wise MLE of some univariate distributions

Column-wise MLE of some univariate distributions

Description

Column-wise MLE of some univariate distributions.

Usage

```
collognorm.mle(x)
collogitnorm.mle(x)
colborel.mle(x)
colhalfnorm.mle(x)
colordinal.mle(x, link = "logit")
colcauchy.mle(x, tol = 1e-07, maxiters = 100, parallel = FALSE)
colbeta.mle(x, tol = 1e-07, maxiters = 100, parallel = FALSE)
colunitweibull.mle(x, tol = 1e-07, maxiters = 100, parallel = FALSE)
```

Arguments

х	A numerical matrix with data. Each column refers to a different vector of observations of the same distribution. The values of for Lognormal must be greater than zero, for the logitnormal they must by percentages, exluding 0 and 1, whereas for the Borel distribution the x must contain integer values greater than 1. For the halfnormal the numbers must be strictly positive, while for the ordinal this can be a numerical matrix with values 1, 2, 3,, not zeros.
link	This can either be "logit" or "probit". It is the link function to be used.
tol	The tolerance value to terminate the Newton-Fisher algorithm.
maxiters	The maximum number of iterations to implement.
parallel	Do you want to calculations to take place in parallel? The default value is FALSE

Details

For each column, the same distribution is fitted and its parameters and log-likelihood are computed.

Value

A matrix with two or three columns. The first one or the first two contain the parameter(s) of the distribution and the second or third column the relevant log-likelihood. For the ordinal a list including:

param A matrix with the intercepts (threshold coefficients) of the model applied to each

column (or variable).

loglik The log-likelihood values.

Column-wise MLE of the angular Gaussian distribution

Column-wise MLE of the angular Gaussian distribution

Description

Column-wise MLE of the angular Gaussian distribution.

Usage

```
colspml.mle(x ,tol = 1e-07, maxiters = 100, parallel = FALSE)
```

Arguments

X	A numerical matrix with data. Each column refers to a different vector of observations of the same distribution. The values of for Lognormal must be greater than zero, for the logitnormal they must by percentages, exluding 0 and 1, whereas for the Borel distribution the x must contain integer values greater than 1.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
maxiters	The maximum number of iterations that can take place in each regression.
parallel	Do you want this to be executed in parallel or not. The parallel takes place in C++, and the number of threads is defined by each system's available cores.

Details

For each column, spml.mle function is applied that fits the angular Gaussian distribution estimates its parameters and computes the maximum log-likelihood.

Value

A matrix with four columns. The first two are the mean vector, then the γ parameter, and the fourth column contains maximum log-likelihood.

Column-wise pooled variances across groups

Column-wise pooled variances across groups

Description

Column-wise pooled variances across groups.

Usage

```
pooled.colVars(x, ina, std = FALSE)
```

Arguments

X	A matrix with the data.
ina	A numerical vector specifying the groups. If you have numerical values, do not put zeros, but $1, 2, 3$ and so on.
std	A boolean variable specyfying whether you want the variances (FALSE) or the standard deviations (TRUE) of each column.

Details

This function cacluates the pooled variance (or standard deviation) for a range of groups for each column.

Value

A vector with the pooled column variances or standard deviations.

Author(s)

Michail Tsagris.

See Also

colmeansvars

```
pooled.colVars( as.matrix(iris[, 1:4]), as.numeric(iris[, 5]) )

Column-wise summary statistics with grouping variables

Column-wise summary statistics with grouping variables

Description

Column-wise summary statistics with grouping variables.

Usage

```
colGroup(x,ina,method="sum",names=TRUE, std = FALSE)
```

Arguments

x	A matrix with data.
ina	A numerical vector specifying the groups. If you have numerical values, do not put zeros, but 1, 2, 3 and so on. The numbers must be consecutive , like 1,2,3, Do not put 1, 3, 4 as this will cause C++ to crash.
method	One of the: "sum", "min", "max", "median", "var".
names	Set the name of the result vector with the unique numbers of group variable.
std	A boolean variable specyfying whether you want the variances (FALSE) or the standard deviations (TRUE) of each column. This is taken into account only when method = "var".

Value

Column wise of grouping variables. You can also include diagonal to the check.

```

Conditional least-squares estimate for Poisson INAR(1) models

Conditional least-squares estimate for Poisson INAR(1) models

Description

Conditional least-squares estimate for Poisson INAR(1) models.

Usage

```
pinar1(x, unbiased = FALSE)
colpinar1(x, unbiased = FALSE)
```

Arguments

x Either a numerical vector or a matrix, depending on the function.

unbiased If you want the unbiased estimation select TRUE.

Details

The function computes the constant and slope coefficients of the Poisson Integer Autoregressive of order 1 (Poisson INAR(1)) model using the conditional least-squares method.

Value

For pinar1() a vector with two values, the λ coefficient (constant) and the α coefficient (slope). See references for more information.

For the colpinar1() a matrix with two columns, the λ coefficient (constant) and the α coefficient (slope) for each variable (column of x).

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

Constrained least squares

Constrained least squares

Description

Constrained least squares.

Usage

```
cls(y, x, R, ca)
```

Arguments

y The response variables, a numerical vector with observations.

x A matrix with independent variables, the design matrix.

R The R vector that contains the values that will multiply the beta coefficients. See

details and examples.

ca The value of the constraint, $R^T \beta = c$. See details and examples.

Details

This is described in Chapter 8.2 of Hansen (2019). The idea is to inimise the sum of squares of the residuals under the constraint $R^T\beta=c$. As mentioned above, be careful with the input you give in the x matrix and the R vector.

Value

A list including:

bols The OLS (Ordinary Least Squares) beta coefficients.
bcls The CLS (Constrained Least Squares) beta coefficients.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

cls(y, x, R, 1)</pre>
```

Contour plots of some bivariate distributions

Contour plots of some bivariate distributions

Description

Contour plots of some bivariate distributions.

Usage

```
den.contours(x, type = "normal", v = 5)
```

Arguments

x A matrix with two columns containing the data.

type The distribution whose contours will appear. This can be "normal", "t" or "ml-

norm", standing for the bivariate normal, t and bivariate log-normal.

v The degrees of freedom of the bivariate t distribtuion.

Value

The contour plot.

Correlation significance testing using Fisher's z-transformation

Correlation significance testing using Fisher's z-transformation

Description

Correlation significance testing using Fisher's z-transformation.

Usage

```
cor_test(y, x, type = "pearson", rho = 0, a = 0.05)
```

Arguments

у	A numerical vector.
X	A numerical vector.
type	The type of correlation you want. "pearson" and "spearman" are the two supported types because their standard error is easily calculated.
rho	The value of the hypothesised correlation to be used in the hypothesis testing.
а	The significance level used for the confidence intervals.

Details

The function uses the built-in function "cor" which is very fast, then computes a confidence interval and produces a p-value for the hypothesis test.

Value

A vector with 5 numbers; the correlation, the p-value for the hypothesis test that each of them is equal to "rho", the test statistic and the a/2% lower and upper confidence limits.

Cross-validation for the k-NN algorithm for really lage scale data

Cross-validation for the k-NN algorithm for really lage scale data

Description

Cross-validation for the k-NN algorithm for really lage scale data.

Usage

```
bigknn.cv(y, x, k = 5:10, type = "C", folds = NULL, nfolds = 10,
stratified = TRUE, seed = FALSE, pred.ret = FALSE)
```

Arguments

У	A vector of data. The response variable, which can be either continuous or categorical (factor is acceptable).
X	A matrix with the available data, the predictor variables.
k	A vector with the possible numbers of nearest neighbours to be considered.
type	If your response variable y is numerical data, then this should be "R" (regression). If y is in general categorical set this argument to "C" (classification).
folds	A list with the indices of the folds.
nfolds	The number of folds to be used. This is taken into consideration only if "folds" is NULL.
stratified	Do you want the folds to be selected using stratified random sampling? This preserves the analogy of the samples of each group. Make this TRUE if you wish, but only for the classification. If you have regression (type = "R"), do not put this to TRUE as it will cause problems or return wrong results.
seed	If you set this to TRUE, the same folds will be created every time.
pred.ret	If you want the predicted values returned set this to TRUE.

Details

The concept behind k-NN is simple. Suppose we have a matrix with predictor variables and a vector with the response variable (numerical or categorical). When a new vector with observations (predictor variables) is available, its corresponding response value, numerical or categorical, is to be predicted. Instead of using a model, parametric or not, one can use this ad hoc algorithm.

The k smallest distances between the new predictor variables and the existing ones are calculated. In the case of regression, the average, median, or harmonic mean of the corresponding response values of these closest predictor values are calculated. In the case of classification, i.e. categorical response value, a voting rule is applied. The most frequent group (response value) is where the new observation is to be allocated.

This function does the cross-validation procedure to select the optimal k, the optimal number of nearest neighbours. The optimal in terms of some accuracy metric. For the classification it is the percentage of correct classification and for the regression the mean squared error.

This function allows for the Euclidean distance only.

Value

A list including:

preds If pred.ret is TRUE the predicted values for each fold are returned as elements

in a list.

crit A vector whose length is equal to the number of k and is the accuracy metric for

each k. For the classification case it is the percentage of correct classification.

For the regression case the mean square of prediction error.

Cross-validation for the multinomial regression

Cross-validation for the multinomial regression

Description

Cross-validation for the multinomial regression.

Usage

Arguments

y The response variable.	A numerical or a factor type vector.
--------------------------	--------------------------------------

x A matrix or a data.frame with the predictor variables.

folds A list with the indices of the folds.

nfolds The number of folds to be used. This is taken into consideration only if "folds"

is NULL.

stratified Do you want the folds to be selected using stratified random sampling? This

preserves the analogy of the samples of each group. Make this TRUE if you wish, but only for the classification. If you have regression (type = "R"), do not

put this to TRUE as it will cause problems or return wrong results.

seed If you set this to TRUE, the same folds will be created every time.

pred.ret If you want the predicted values returned set this to TRUE.

Value

A list including:

preds If pred.ret is TRUE the predicted values for each fold are returned as elements

in a list.

crit A vector whose length is equal to the number of k and is the accuracy metric for

each k. For the classification case it is the percentage of correct classification.

```

Examples

```
x <- as.matrix(iris[, 1:4])
mod <- nb.cv(ina = iris[, 5], x = x )</pre>
```

Description

Cross-validation for the regularised maximum likelihood linear discriminant analysis.

Usage

```
regmlelda.cv(x, ina, lambda = seq(0, 1, by = 0.1), folds = NULL, nfolds = 10, stratified = TRUE, seed = FALSE, pred.ret = FALSE)
```

Arguments

X	A matrix with numerical data.
ina	A numerical vector or factor with consecutive numbers indicating the group to which each observation belongs to.
lambda	A vector of regularization values λ such as $(0, 0.1, 0.2,)$.
folds	A list with the indices of the folds.
nfolds	The number of folds to be used. This is taken into consideration only if "folds" is NULL.
stratified	Do you want the folds to be selected using stratified random sampling? This preserves the analogy of the samples of each group. Make this TRUE if you wish, but only for the classification. If you have regression (type = "R"), do not put this to TRUE as it will cause problems or return wrong results.
seed	If you set this to TRUE, the same folds will be created every time.
pred.ret	If you want the predicted values returned set this to TRUE.

Details

Cross-validation for the regularised maximum likelihood linear discriminant analysis is performed. The function is not extremely fast, yet is pretty fast.

Value

A list including:

preds If pred.ret is TRUE the predicted values for each fold are returned as elements

in a list.

crit A vector whose length is equal to the number of k and is the accuracy metric for

each k. For the classification case it is the percentage of correct classification.

For the regression case the mean square of prediction error.

Diagonal values of the Hat matrix

Diagonal values of the Hat matrix

Description

Diagonal values of the Hat matrix.

Usage

```
leverage(x)
```

Arguments

Χ

A matrix with independent variables, the design matrix.

Details

The function returns the diagonal values of the Hat matrix used in linear regression. We did not call it "hatvalues" as R contains a built-in function with such a name.

Value

A vector with the diagonal Hat matrix values, the leverage of each observation.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

Distance between two covariance matrices

Distance between two covariance matrices

Description

Distance between two covariance matrices.

Usage

```
covdist(s1, s2)
```

Arguments

- s1 The firt covariance matrix.
- The second covariance matrix.

Distance correlation matrix

Details

A metric for covariance matrices is the title of a paper by Forstner and Moonen (2003). The metric is computed for two non-singular covariance matrices.

39

Value

The distance between the two covariance matrices.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```

Empirical entropy

Empirical entropy

Description

Empirical entropy.

Usage

```
empirical.entropy(x, k = NULL, pretty = FALSE)
```

Arguments

x A numerical vector with continuous values.

k If you want to cut the data into a specific range plug it here, otherwise this decide

based upon the Freedman-Diaconis' rule.

pretty Should the breaks be equally space upon the range of x? If yes, let this FALSE.

If this is TRUE, the breaks are decided using the base command pretty.

Details

The function computes the empirical entropy.

Value

The estimated empirical entropy.

Fisher's linear discriminant analysis

Fisher's linear discriminant analysis

Description

Fisher's linear discriminant analysis.

Usage

```
fisher.da(xnew, x, ina)
```

Arguments

xnew A numerical vector or a matrix with the new observations, continuous data.

x A matrix with numerical data.

ina A numerical vector or factor with consecutive numbers indicating the group to

which each observation belongs to.

Details

Maximum likelihood linear discriminant analysis is performed.

Value

A vector with the predicted group of each observation in "xnew".

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```

Fixed effects regression

Fixed effects regression

Description

Fixed effects regression.

Usage

```
fe.lmfit(y, x, id)
```

Arguments

y A numerical vector or a numerical matrix.

x A numerical matrix with the predictor variables.

id A vector with the subject ids. This can be factor or a numerical.

Details

The function performs fixed effects regression (within estimator) for panel (longitudinal) data. It can also handle unblanced designs. A main difference from the package "plm" is that it returns much fewer information, but much faster.

Value

A list including:

be The beta coefficients.

fe The fixed effect deviations.

residuals The residuals of the linear model(s).

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

Fixed intercepts Poisson regression

Fixed intercepts Poisson regression

Description

Fixed intercepts Poisson regression.

Usage

```
fipois.reg(y, x, id, tol = 1e-07, maxiters = 100)
```

Arguments

у	The dependent variable, a numerical vector with integer, non negative valued data.
X	A matrix with the indendent variables.
id	A numerical variable with 1, 2, indicating the subject. Unbalanced design is of course welcome.
tol	The tolerance value to terminate the Newton-Raphson algorithm. This is set to 10^{-7} by default.
maxiters	The maximum number of iterations that can take place during the fitting.

Details

Fixed intercepts Poisson regression for clustered count data is fitted. According to Demidenko (2013), when the number of clusters (N) is small and the number of observations per cluster (n_i) is relatively large, say $min(n_i) > N$, one may assume that the intercept $\alpha_i = \beta + u_i$ is fixed and unknown (i = 1, ..., N).

Value

A list including:

be The regression coefficients.

seb The standard errors of the regression coefficients.

ai The estimated fixed intercepts fore ach cluster of observations.

covbeta The covariance matrix of the regression coefficients.

loglik The maximised log-likelihood value.

iters The number of iteration the Newton-Raphson required.

Forward Backward Early Dropping selection regression

Forward Backward Early Dropping selection regression

Description

Forward Backward Early Dropping selection regression.

Usage

Arguments

У	The response variable, a numeric vector.
X	A matrix with continuous variables.
alpha	The significance threshold value for assessing p-values. Default value is 0.05.
type	The available types are: "logistic" (binary logistic regression), "qlogistic" (quasi logistic regression, for binary value or proportions including 0 and 1), "poisson" (Poisson regression), "qpoisson" (quasi Poisson regression), "weibull" (Weibull regression) and "spml" (SPML regression).
K	How many times should the process be repeated? The default value is 0.
backward	After the Forward Early Dropping phase, the algorithm proceeds with the usual Backward Selection phase. The default value is set to TRUE. It is advised to perform this step as maybe some variables are false positives, they were wrongly selected. This is rather experimental now and there could be some mistakes in the indices of the selected variables. Do not use it for now.
parallel	If you want the algorithm to run in parallel set this TRUE.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
maxiters	The maximum number of iterations Newton-Raphson will perform.

Details

The algorithm is a variation of the usual forward selection. At every step, the most significant variable enters the selected variables set. In addition, only the significant variables stay and are further examined. The non significant ones are dropped. This goes until no variable can enter the set. The user has the option to re-do this step 1 or more times (the argument K). In the end, a backward selection is performed to remove falsely selected variables. Note that you may have specified, for example, K=10, but the maximum value FBED used can be 4 for example.

The "qlogistic" and "qpoisson" proceed with the Wald test and no backward is performed, while for all the other regression types, the log-likelihood ratio test is used and backward phase is available.

Value

If K is a single number a list including:

Note, that the "gam" argument must be the same though.

res A matrix with the selected variables and their test statistic.

info A matrix with the number of variables and the number of tests performed (or

models fitted) at each round (value of K). This refers to the forward phase only.

runtime The runtime required.

Author(s)

Examples

```
#simulate a dataset with continuous data x \leftarrow matrix( runif(100 * 50, 1, 100), ncol = 50 ) y \leftarrow rnbinom(100, 10, 0.5) a \leftarrow fbed.reg(y, x, type = "poisson")
```

Fractional polynomial regression with one independent variable

Fractional polynomial regression with one independent variable.

Description

Fractional polynomial regression with one independent variable.

Usage

```
fp(y, x, aa, di = NULL, type = "normal", full = FALSE, seb = FALSE,
tol = 1e-07, maxiters = 100)
```

Arguments

У	The dependent variable, a numerical vector.
X	A vector, the independent variable.
aa	A vector with two values indicating the range of the optimal value of $\boldsymbol{\alpha}$ to search within.
di	This is valid only for the Weibull regression. A vector with 1s and 0s indicating the censored value. The value of 1 means uncesored value, whereas the value of 0 means censored value.
type	The type of regression model: "normal", "logistic", "poisson", "spml" (SPML regression), "gamma", "normlog", "weibull", "negbin".
full	If this is FALSE, the coefficients and the deviance will be returned only. If this is TRUE, more information is returned.
seb	Do you want the standard error of the estimates to be returned? TRUE or FALSE.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
maxiters	The max number of iterations that can take place in each regression.

Details

The independent variable is power transformed and this function searches for the optimal power.

Value

A list including:

a The power that yields the optimal fit.

mod The model with the independent variable power transformed.

```

Gamma regression with a log-link

Gamma regression with a log-link

Description

Gamma regression with a log-link.

Usage

```
gammareg(y, x, tol = 1e-07, maxiters = 100)
```

Arguments

y The dependent variable, a numerical variable with non negative numbers.

x A matrix or data.frame with the indendent variables.

tol The tolerance value to terminate the Newton-Raphson algorithm.

maxiters The maximum number of iterations that can take place in the regression.

Details

The gamma.reg fits a Gamma regression with a log-link. The gamma.con fits a Gamma regression with a log link with the intercept only ($glm(y \sim 1, Gamma(log))$).

Value

A list including:

iters The number of iterations required by the newton-Raphson.

deviance The deviance value.

phi The dispersion parameter (ϕ) of the regression. This is necessary if you want

to perform an F hypothesis test for the significance of one or more independent

variables.

be The regression coefficient(s).

m2 <- gammareg(y, x)
## End(Not run)</pre>
```

GEE Gaussian regression

GEE Gaussian regression

Description

GEE Gaussian regression.

Usage

```
gee.reg(y, x, id, tol = 1e-07, maxiters = 100)
```

Arguments

У	The dependent variable, a numerical vector.
X	A matrix with the indendent variables.
id	A numerical variable with 1, 2, indicating the subject. Unbalanced design is of course welcome.
tol	The tolerance value to terminate the Newton-Raphson algorithm. This is set to 10^{-7} by default.
maxiters	The maximum number of iterations that can take place during the fitting.

Details

Gaussin GEE regression is fitted.

Value

A list including:

be The regression coefficients.

seb The standard errors of the regression coefficients.

phi The ϕ parameter.

50 Gumbel regression

a The α parameter.

covbeta The covariance matrix of the regression coefficients.

iters The number of iteration the Newton-Raphson required.

x <- rnorm(200, 3)
gee.reg(y, x, id)</pre>
```

Gumbel regression

Gumbel regression

Description

Gumbel regression.

Usage

```
gumbel.reg(y, x, tol = 1e-07, maxiters = 100)
```

Arguments

y The dependent variable, a numerical vector with real valued numbers.

x A matrix or a data.frame with the indendent variables.

tol The tolerance value required by the Newton-Raphson to stop.

maxiters The maximum iterations allowed.

Details

A Gumbel regression model is fitted. the standard errors of the regressions are not returned as we do not compute the full Hessian matrix at each step of the Newton-Raphson.

Value

A list including:

be The regression coefficients.

sigma The scale parameter.

loglik The loglikelihood of the regression model.

iters The iterations required by the Newton-Raphson.

Hellinger distance based regression for count data

Hellinger distance based regression for count data

Description

Hellinger distance based regression for count data.

Usage

```
hellinger.countreg(y, x, tol = 1e-07, maxiters = 100)
```

Arguments

У	The dependent variable, a numerical vector with integer valued data, counts.
X	A numerical matrix with the indendent variables. We add, internally, the first column of ones.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
maxiters	The max number of iterations that can take place in each regression.

Details

We minimise the Hellinger distance instead of the ordinarily used divergence, the Kullback-Leibler. Both of them fall under the ϕ -divergence class models and hance this one produces asympottically normal regression coefficients as well.

Value

A list including:

be	The regression coefficients.
seb	The sandwich standard errors of the coefficients.
covbe	The sandwich covariance matrix of the regression coefficients.
Н	The final Hellinger distance.
iters	The number of iterations required by Newton-Raphson.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```

Hellinger distance based univariate regression for proportions

Hellinger distance based univariate regression for proportions

Description

Hellinger distance based univariate regression for proportions.

Usage

```
prophelling.reg(y, x, cov = FALSE, tol = 1e-07, maxiters = 100)
```

Arguments

у	The dependent variable, a numerical vector with percentages.
x	A numerical matrix with the indendent variables. We add, internally, the first column of ones.
cov	Should the sandwich covariance matrix and the standard errors be returned? If yes, set this equal to TRUE.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
maxiters	The max number of iterations that can take place in each regression.

Details

We minimise the Jensen-Shannon divergence instead of the ordinarily used divergence, the Kullback-Leibler. Both of them fall under the ϕ -divergence class models and hance this one produces asympottically normal regression coefficients as well.

Value

A list including:

be	The regression coefficients.
seb	The sandwich standard errors of the beta coefficients, if the input argument argument was set to TRUE.
covb	The sandwich covariance matrix of the beta coefficients, if the input argument argument was set to TRUE.
js	The final Jensen-Shannon divergence.
Н	The final Hellinger distance.
iters	The number of iterations required by Newton-Raphson.

Heteroscedastic linear models for large scale data

Heteroscedastic linear models for large scale data

Description

Heteroscedastic linear models for large scale data.

Usage

```
het.lmfit(x, y, type = 1)
```

Arguments

x The design matrix with the data, where each column refers to a different sample of subjects. You must supply the design matrix, with the column of 1s. This function is the analogue of lm.fit and .lm.fit.

y A numerical vector or a numerical matrix.

type The type of regression to be fit in order to find the weights. The type 1 is described in Wooldridge (2012, page 287), whereas type 2 is described in page

Wooldridge (2012, page 287).

Details

We have simply exploitted R's powerful function and managed to do better than .lm.fit which is a really powerful function as well. This is a bare bones function as it returns only two things, the coefficients and the residuals. .lm.fit returns more and lm.fit even more and finally lm returns too much. The addition is that we allow for estimation of the regression coefficients when heteroscedasticity is present.

Value

A list including:

The beta coefficients.

residuals The residuals of the linear model(s).

x <- NULL
```

Hurdle-Poisson regression

Hurdle-Poisson regression

Description

Hurdle-Poisson regression.

Usage

```
hp.reg(y, x, full = FALSE, tol = 1e-07, maxiters = 100)
```

Arguments

У	The dependent variable, a numerical vector with numbers.
x	A numerical matrix with the indendent variables. We add, internally, the first
	column of ones.
full	If this is FALSE, the coefficients and the log-likelihood will be returned only. If

this is TRUE, more information is returned.

tol The tolerance value to terminate the Newton-Raphson algorithm. The max number of iterations that can take place in each regression. maxiters

Details

Two regression models are fitted, a binary logistic regression and a zero truncated Poisson regression model.

Value

Depending on whether "full" is TRUE or not different outputs are returned. In general, the regression coefficients, the iterations required by Newton-Raphson and the deviances are returned. If full is TRUE, a matrix with their standard errors and the Wald test statistics is returned as well.

Hypothesis tests for equality of a covariance matrix

Hypothesis tests for equality of a covariance matrix

Description

Hypothesis tests for equality of a covariance matrix.

Usage

```
covequal(x, sigma, a = 0.05)
```

Arguments

x A numerical matrix with the data whose covariance matrix will be tested for equality.

sigma The covariance matrix that is to be tested for equality.

a The level of significance, default value is equal to 0.05.

Details

The likelihood-ratio test is used to test whether the sample covariance matrix from some data is equal to some pre-specifief covariance matrix.

Value

A vector with the test statistic, its p-value, the degrees of freedom and the critical value of the test.

Hypothesis tests for equality of multiple covariance matrices

Hypothesis tests for equality of multiple covariance matrices

Description

Hypothesis tests for equality of multiple covariance matrices.

Usage

```
covlikel(x, ina, a = 0.05)
covmtest(x, ina, a = 0.05)
```

Arguments

x A numerical matrix with the data whose covariance matrices will be tested for equality.

ina A vector with the grouping variable that defines the groups.

a The level of significance, default value is equal to 0.05.

58 Intersect

Details

The likelihood-ratio test and the Box's M-test for testing equality of multiple covariance matrices. The log-likelihood ratio test is the multivariate generalization of Bartlett's test of homogeneity of variances. According to Mardia (1979, pg. 140), it may be argued that if n_i is small, then the log-likelihood ratio test gives too much weight to the contribution of S. This consideration led Box (1949) to propose his test statistic.

Value

A vector with the test statistic, its p-value, the degrees of freedom and the critical value of the test.

Intersect

Intersect Operation

Description

Performs intersection in the same manner as R's base package intersect works.

Usage

```
Intersect(x, y)
```

Arguments

х, у

vectors containing a sequence of items, ideally of the same mode

Details

The function will discard any duplicated values in the arguments.

Value

The function will return a vector of the same mode as the arguments given. NAs will be removed.

Item difficulty and discrimination

Item difficulty and discrimination

Description

Item difficulty and discrimination.

Usage

```
diffic(x)
discrim(x, frac = 1/3)
```

Arguments

x A numerical matrix with 0s (wrong answer) and 1s (correct answer).

frac A number between 0 and 1 used to calculate the difficulty of each question.

Details

The difficulty and the discrimination of each question (item) are calculated.

Value

A vector with the item difficulties or item discriminations.

Kaplan-Meier estimate of a survival function

Kaplan-Meier estimate of a survival function

Description

Kaplan-Meier estimate of a survival function.

Usage

```
km(ti, di)
```

Arguments

ti A numerical vector with the survival times.

di A numerical vector indicating the censorings. 0 = censored, 1 = not censored.

Details

The Kaplan-Meier estimate of the survival function takes place.

Value

A matrix with 4 columns. The non censored times, the number of subjects at risk, the number of events at each time and the estimated survival

Linear regression with clustered data

Linear regression with clustered data

Description

Linear regression with clustered data.

Usage

```
cluster.lm(y, x, id)
```

Arguments

y The dependent variable, a numerical vector with numbers.

A matrix or a data frame with the indendent variables.

id A numerical variable with 1, 2, ... indicating the subject. Unbalanced design is

of course welcome.

Details

A linear regression model for clustered data is fitted. For more information see Chapter 4.21 of Hansen (2019).

Value

A list including:

be The (beta) regression coefficients.

becov Robust covariance matrix of the regression coefficients.

seb Robust standard errors of the regression coefficients.

```

Mahalanobis depth

Mahalanobis depth

Description

Mahalanobis depth.

Usage

```
depth.mahala(x, data)
```

Arguments

x A numerical vector or matrix whose depth you want to compute.

data A numerical matrix used to compute the depth of x.

Details

This function computes the Mahalanobis depth of x with respect to data.

Value

A numevrical vector with the Mahalanobis depth for each value of x.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```
Many 2 sample student's t-tests
```

Many 2 sample student's t-tests

Description

It performs very many 2 sample student's t-tests.

Usage

```
stud.ttests(x, y = NULL, ina, logged = FALSE, parallel = FALSE)
```

Arguments

X	A matrix with the data, where the rows denote the samples and the columns are the variables.
у	A second matrix with the data of the second group. If this is NULL (default value) then the argument ina must be supplied. Notice that when you supply the two matrices the procedure is two times faster.
ina	A numerical vector with 1s and 2s indicating the two groups. Be careful, the function is designed to accept only these two numbers. In addition, if your " y " is NULL, you must specify "ina".
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?
parallel	Should parallel implentations take place in C++? The default value is FALSE.

Details

For the t-tests, the student's t-test (that assumes equal variances) is performed.

Value

A matrix with the test statistic, the degrees of freedom and the p-value (or their logarithm) of each test

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```

Many approximate simple logistic regressions

Many approximate simple logistic regressions.

Description

Many approximate simple logistic regressions.

Usage

```
sp.logiregs(y, x, logged = FALSE)
```

Arguments

y The dependent variable, a numerical vector with 0s or 1s.

x A matrix with the indendent variables.

logged Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

Many simple approximate logistic regressions are performed and hypothesis testing for the singificance of each coefficient is returned. The code is available in the paper by Sikorska et al. (2013). We simply took the code and made some minor modifications. The explanation and the motivation can be found in their paper. They call it semi-parallel logistic regressions, hence we named the function sp.logiregs.

Value

A two-column matrix with the test statistics (Wald statistic) and their associated p-values (or their logarithm).

Author(s)

Initial author Karolina Sikorska. Modifications by Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```

Many binary classification metrics

Many binary classification metrics

Description

Many binary classification metrics.

Usage

```
colaccs(group, preds)
colsens(group, preds)
colspecs(group, preds)
colprecs(group, preds)
colfscores(group, preds)
colfbscores(group, preds, b)
colfmis(group, preds)
```

Arguments

group A numerical vector with two values, 0 and 1.

preds A numerical matrix with scores, probabilities or any other measure.

b The β parameter in the F_{β} -score.

Details

The accuracies, sensitivities, specificities, precisions, F-scores, F_{β} -scores and the Fowlkes-Mallows index are calculated column-wise. The colaccs is the only metric that can be used with a multinomial response as well.

Value

A vector with length equal to the number of columns of the "preds" argument containing the relevant values computed for each column.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```

Many Gamma regressions

Many Gamma regressions

Description

Many Gamma regressions.

Usage

```
gammaregs(y, x, tol = 1e-07, logged = FALSE, parallel = FALSE, maxiters = 100)
```

Arguments

у	The dependent variable, a numerical variable with non negative numbers for the Gamma and inverse Gaussian regressions. For the Gaussian with a log-link zero values are allowed.
x	A matrix with the indendent variables.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
logged	A boolean variable; it will return the logarithm of the pvalue if set to TRUE.
parallel	Do you want this to be executed in parallel or not. The parallel takes place in C++, therefore you do not have the option to set the number of cores.
maxiters	The maximum number of iterations that can take place in each regression.

Details

Many simple Gamma regressions with a log-link are fitted.

Value

A matrix with the test statistic values and their relevant (logged) p-values.

Author(s)

Stefanos Fafalios and and Michail Tsagris.

R implementation and documentation: Stefanos Fafalios <stefanosfafalios@gmail.com> and Michail Tsagris <mtsagris@uoc.gr>.

Many metrics for a continuous response variable

any metrics for a continuous response variable

Description

any metrics for a continuous response variable.

Usage

```
colmses(y, yhat, parallel = FALSE)
colmaes(y, yhat, parallel = FALSE)
colpkl(y, yhat, parallel = FALSE)
colukl(y, yhat, parallel = FALSE)
```

Arguments

y A numerical vector.

yhat A numerical matrix with with the predictions.

parallel If you want parallel computations set this equal to TRUE.

Details

The mean squared errors, mean absolute errors, and Kullback-Leibler divergence for percentages (colpkl) and non-negative values or discrete values (colukl) are computed.

Value

A vector with length equal to the number of columns of the "yhat" argument containing the relevant values computed for each column.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

## 20 variables, hence 20 MSEs will be calculated y <- rnorm(100, 1, 0.6) yhat <- matrix( rnorm(100 * 20), ncol = 20 ) a <- colmses(y, yhat)
```

Many negative binomial regressions

Many negative binomial regressions

Description

Many negative binomial regressions.

Usage

```
negbin.regs(y, x, type = 1, tol = 1e-07, logged = FALSE, parallel = FALSE, maxiters = 100)
```

Arguments

У	The dependent variable, a numerical variable with non negative numbers
х	A matrix with the indendent variables.
type	You can choose which way your prefer. Type 1 is for smal sample sizes, whereas type 2 is for larger ones as is faster.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
logged	If you want the logarithm of the p-values set this equal to TRUE.
parallel	Do you want this to be executed in parallel or not. The parallel takes place in C++, therefore you do not have the option to set the number of cores.
maxiters	The maximum number of iterations that can take place in each regression.

Details

Many simple negative binomial regressions with a log-link are fitted.

Value

A matrix with the test statistic values and their relevant (logged) p-values.

Author(s)

Stefanos Fafalios and and Michail Tsagris.

R implementation and documentation: Stefanos Fafalios <stefanosfafalios@gmail.com> and Michail Tsagris <mtsagris@uoc.gr>.

```

Many score based regressions with muliple response variables and a single predictor variable

Many score based regressions with muliple response variables and a

single predictor variable

Description

Many score based regressions with muliple response variables and a single predictor variable.

Usage

```
mv.score.glms(y, x, oiko = NULL, logged = FALSE)
mv.score.weibregs(y, x, logged = FALSE)
mv.score.betaregs(y, x, logged = FALSE)
mv.score.gammaregs(y, x, logged = FALSE)
mv.score.expregs(y, x, logged = FALSE)
mv.score.invgaussregs(y, x, logged = FALSE)
```

Arguments

A matrix with either discrete or binary data for the Poisson or binary logistic regression respectively. For the Weibull, gamma, inverse Gaussian and exponential regressions the values of y must be strictly positive data, lifetimes or durations for example. For the beta regression they must be numbers between 0 and 1.

x A vector with continuous data, the predictor variable.

oiko This can be either "poisson" or "binomial".

logged A boolean variable; it will return the logarithm of the pvalue if set to TRUE.

Details

Instead of maximising the log-likelihood via the Newton-Raphson algorithm in order to perform the hypothesis testing that $\beta_i=0$ we use the score test. This is dramatcially faster as no model needs to be fitted. The first derivative (score) of the log-likelihood is known and in closed form and under the null hypothesis the fitted values are all equal to the mean of the response variable y. The variance of the score is also known in closed form. The test is not the same as the likelihood ratio test. It is size correct nonetheless but it is a bit less efficient and less powerful. For big sample sizes though (5000 or more) the results are the same. We have seen via simulation studies is that it is size correct to large sample sizes, at elast a few thousands. You can try for yourselves and see that even with 500 the results are pretty close. The score test is pretty faster then the classical log-likelihood ratio test.

Value

A matrix with two columns, the test statistic and its associated p-value. For the Poisson and logistic regression the p-value is derived via the t distribution, whereas for all other regression models via the χ^2 distribution.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

Many score based zero inflated Poisson regressions

Many score based zero inflated Poisson regressions

Description

Many score based zero inflated Poisson regressions.

Usage

```
score.zipregs(y, x, logged = FALSE )
```

Arguments

y A vector with discrete data, counts.

x A matrix with data, the predictor variables.

logged A boolean variable; it will return the logarithm of the pvalue if set to TRUE.

Details

Instead of maximising the log-likelihood via the Newton-Raphson algorithm in order to perform the hypothesis testing that $\beta_i=0$ we use the score test. This is dramatically faster as no model need to be fitted. The first derivative of the log-likelihood is known in closed form and under the null hypothesis the fitted values are all equal to the mean of the response variable y. The test is not the same as the likelihood ratio test. It is size correct nonetheless but it is a bit less efficient and less powerful. For big sample sizes though (5000 or more) the results are the same. It is also much faster then the classical likelihood ratio test.

```

Many simple quantile regressions using logistic regressions

Many simple quantile regressions using logistic regressions.

Description

Many simple quantile regressions using logistic regressions.

Usage

```
logiquant.regs(y, x, logged = FALSE)
```

Arguments

y The dependent variable, a numerical vector.

x A matrix with the indendent variables.

logged Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

Instead of fitting quantile regression models, one for each predictor variable and trying to assess its significance, Redden et al. (2004) proposed a simple singificance test based on logistic regression. Create an indicator variable I where 1 indicates a response value above its median and 0 elsewhere. Since I is binary, perform logistic regression for the predictor and assess its significance using the likelihood ratio test. We perform many logistic regression models since we have many predictors whose univariate association with the response variable we want to test.

Value

A two-column matrix with the test statistics (likelihood ratio test statistic) and their associated p-values (or their logarithm).

Author(s)

Author: Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

a <- logiquant.regs(y, x)</pre>
```

Many simple Weibull regressions

Many simple Weibull regressions.

Description

Many simple Weibull regressions.

Usage

```
weib.regs(y, x, tol = 1e-07, logged = FALSE, parallel = FALSE, maxiters = 100)
```

Arguments

у	The dependent variable, either a numerical variable with numbers greater than zero.
X	A matrix with the indendent variables.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
logged	A boolean variable; it will return the logarithm of the pvalue if set to TRUE.
parallel	Do you want this to be executed in parallel or not. The parallel takes place in C++, and the number of threads is defined by each system's available cores.
maxiters	The maximum number of iterations that can take place in each regression.

76 Many Welch tests

Details

Many simple weibull regressions are fitted.

Value

A matrix with the test statistic values and their associated (logged) p-values.

Author(s)

Stefanos Fafalios.

R implementation and documentation: Stefanos Fafalios <stefanosfafalios@gmail.com>.

x <- matrix( rnorm( 100 * 30 ), ncol = 30 )
a <- weib.regs(y, x)
x <- NULL</pre>
```

Many Welch tests

Many Welch tests.

Description

Many Welch tests.

Usage

```
welch.tests(y, x, logged = FALSE, parallel = FALSE)
```

Arguments

У	The dependent variable, a numerical vector.
x	A matrix with the indendent variables. They must be integer valued data starting
	from 1, not 0 and be consecutive numbers. Instead of a data.frame with factor variables, the user must use a matrix with integers.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?
parallel	If you want to run the function in parallel set this equal to TRUE.

Details

For each categorical predictor variable, a Welch test is performed. This is useful in feature selection algorithms, to determine for which variable, the means of the dependent variable differ across the different values.

Value

A two-column matrix with the test statistics (F test statistic) and their associated p-values (or their logarithm).

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```

Max-Min Parents and Children variable selection algorithm for continuous responses

Max-Min Parents and Children variable selection algorithm for continuous responses

Description

Max-Min Parents and Children variable selection algorithm for continuous responses.

Usage

```
mmpc(y, x, max_k = 3, alpha = 0.05, method = "pearson",
ini = NULL, hash = FALSE, hashobject = NULL, backward = FALSE)
```

Arguments

y The class variable. Provide a numeric vector.

x The main dataset. Provide a numeric matrix.

max_k The maximum conditioning set to use in the conditional independence test. Provide an integer.

The default value set is 3.

alpha Threshold for assessing p-values' significance. Provide a double value, between

0.0 and 1.0.

The default value set is 0.05.

method Currently only "pearson" is supported.

ini This argument is used for the avoidance of the univariate associations re-calculations,

in the case of them being present. Provide it in the form of a list.

hash Boolean value for the activation of the statistics storage in a hash type object.

The default value is false.

hashobject This argument is used for the avoidance of the hash re-calculation, in the case of

them being present, similarly to ini argument. Provide it in the form of a hash. Please note that the generated hash object should be used only when the same dataset is re-analyzed, possibly with different values of max_k and alpha.

backward Boolean value for the activation of the backward/symmetry correction phase.

This option removes and falsely included variables in the parents and children set of the target variable. It calls the link{mmpc_bp} for this purpose. The

backward option seems dubious. Please do not use at the moment.

Details

The MMPC function implements the MMPC algorithm as presented in "Tsamardinos, Brown and Aliferis. The max-min hill-climbing Bayesian network structure learning algorithm" http://www.dsl-lab.org/supplements/mmhc_paper/paper_online.pdf

Value

The output of the algorithm is an list including:

selected The order of the selected variables according to the increasing pvalues.

hashobject The hash object containing the statistics calculated in the current run.

pvalues For each feature included in the dataset, this vector reports the strength of its

association with the target in the context of all other variables. Particularly, this vector reports the max p-values found when the association of each variable with the target is tested against different conditional sets. Lower values indicate

higher association.

stats The statistics corresponding to the aforementioned pvalues (higher values indi-

cate higher association).

univ This is a list with the univariate associations; the test statistics and their corre-

sponding logged p-values.

max_k The max_k value used in the current execution.

alpha The alpha value used in the current execution.

n.tests If hash = TRUE, the number of tests performed will be returned. If hash !=

TRUE, the number of univariate associations will be returned.

runtime The time (in seconds) that was needed for the execution of algorithm.

mmpc

Examples

```
set.seed(123)
# Dataset with continuous data
ds <- matrix(runif(100 * 500, 1, 100), ncol = 500)
# Class variable
tar <- 3 * ds[, 10] + 2 * ds[, 100] + 3 * ds[, 20] + rnorm(100, 0, 5)
mmpc(tar, ds, max_k = 3, alpha = 0.05, method = "pearson")</pre>
```

Description

Max-Min Parents and Children variable selection algorithm for non continuous responses.

Usage

```
mmpc2(y, x, max_k = 3, threshold = 0.05, test = "logistic", init = NULL,
tol = 1e-07, backward = FALSE, maxiters = 100, parallel = FALSE)
```

Arguments

У	The response variable, a numeric vector with either count data or binary data.
x	A numerical matrix with the independent (predictor) variables.
max_k	The maximum conditioning set to use in the conditional indepedence test (see Details). Integer, default value is 3.
threshold	Threshold (suitable values in $(0, 1)$) for assessing p-values significance. Default value is 0.05 .
test	One of the following: "logistic", "poisson", "qpoisson".
init	A numeric vector with the logged p-values of the univariate associations. Do not use this at the moment.
tol	The tolerance value to stop the Newtn-Raphson algorithm inside a regression model.
backward	If TRUE, the backward (or symmetry correction) phase will be implemented. This removes any falsely included variables in the parents and children set of the target variable. It calls the link{mmpcbackphase} for this purpose.
maxiters	The maximum number of iterations a Newtn-Raphson algorithm will perform inside a regression model.
parallel	Do you want the computations to take part in parallel? Set TRUE if yes.

Details

MMPC tests each feature for inclusion (selection). It is a variant of the forward selection procedure. a) at every step it removes the non significant variables and does not check thema again. b) Instead of testing a candidate variable conditioning on all previously selected variables, it uses subsets of the previously selected variables. All possible subsets of maximum size equal to max_k. With the approrpiate pre-computations, at every step, it performs only the tests that were not exeucyted before, so it is not that time consuming.

Value

The output of the algorithm is an S3 object including:

selectedVars The selected variables, i.e., the signature of the target variable.

pvalues For each feature included in the dataset, this vector reports the strength of its association with the target in the context of all other variable. Particularly, this vector reports the max p-values found when the association of each variable with the target is tested against different conditional sets. Lower values indicate

higher association.

univ A vector with the logged p-values of the univariate associations. This vector is

very important for subsequent runs of MMPC with different hyper-parameters. After running SES with some hyper-parameters you might want to run MM-PCagain with different hyper-parameters. To avoid calculating the univariate associations (first step) again, you can take this list from the first run of SES and plug it in the argument "ini" in the next run(s) of MMPC. This can speed up the second run (and subequent runs of course) by 50%. See the argument "univ" in

the output values.

kapa_pval A list with the same number of elements as the max\$_k\$. Every element in the

list is a matrix. The first column is the logged p-values, the second column is the variable whose conditional association with the response variable was tested

and the other columns are the conditioning variables.

max_k The max_k option used in the current run.

threshold The threshold option used in the current run.

n.tests The number of tests performed by MMPC will be returned.

runtime The run time of the algorithm. A numeric vector. The first element is the user

time, the second element is the system time and the third element is the elapsed

time.

Maximum likelihood linear discriminant analysis

Maximum likelihood linear discriminant analysis

Description

Maximum likelihood linear discriminant analysis.

Usage

```
mle.lda(xnew, x, ina)
```

Arguments

xnew A numerical vector or a matrix with the new observations, continuous data.

x A matrix with numerical data.

ina A numerical vector or factor with consecutive numbers indicating the group to

which each observation belongs to.

Details

Maximum likelihood linear discriminant analysis is performed.

Value

A vector with the predicted group of each observation in "xnew".

MLE of continuous univariate distributions defined on the positive line $MLE\ of\ continuous\ univariate\ distributions\ defined\ on\ the\ positive\ line$

Description

MLE of continuous univariate distributions defined on the positive line.

Usage

```
halfcauchy.mle(x, tol = 1e-07)
powerlaw.mle(x)
```

Arguments

x A vector with positive valued data (zeros are not allowed).

tol The tolerance level up to which the maximisation stops; set to 1e-09 by default.

Details

Instead of maximising the log-likelihood via a numerical optimiser we have used a Newton-Raphson algorithm which is faster. See wikipedia for the equations to be solved. For the power law we assume that the minimum value of x is above zero in order to perform the maximum likelihood estimation in the usual way.

Value

Usually a list with three elements, but this is not for all cases.

iters The number of iterations required for the Newton-Raphson to converge.

loglik The value of the maximised log-likelihood.

scale The scale parameter of the half Cauchy distribution.

alpha The value of the power parameter for the power law distribution.

x \leftarrow abs( rcauchy(1000, 0, 2) )
halfcauchy.mle(x)
```

MLE of distributions defined for proportions MLE of distributions defined for proportions

Description

MLE of distributions defined for proportions.

Usage

```
kumar.mle(x, tol = 1e-07, maxiters = 50)
simplex.mle(x, tol = 1e-07)
zil.mle(x)
unitweibull.mle(x, tol = 1e-07, maxiters = 100)
cbern.mle(x, tol = 1e-6)
```

Arguments

X	A vector with proportions or percentages. Zeros are allowed only for the zero
	inflated logistire normal distribution (zil.mle).
tol	The tolerance level up to which the maximisation stops.
maxiters	The maximum number of iterations the Newton-Raphson will perform.

Details

Instead of maximising the log-likelihood via a numerical optimiser we have used a Newton-Raphson algorithm which is faster. See wikipedia for the equations to be solved. The distributions are Kumaraswamy, zero inflated logistic normal, simplex, unit Weibull and continuous Bernoulli.

Value

Usually a list with three elements, but this is not for all cases.

iters	The number of iterations required for the Newton-Raphson to converge.
param	The two parameters (shape and scale) of the Kumaraswamy distribution or the means and sigma of the simpled distribution. For the zero inflated logistic normal, the probability of non zeros, the mean and the unbiased variance.
loglik	The value of the maximised log-likelihood.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

MLE of some circular distributions with multiple samples $MLE\ of\ some\ circular\ distributions\ with\ multiple\ samples$

Description

MLE of some circular distributions with multiple samples.

Usage

```
multivm.mle(x, ina, tol = 1e-07, ell = FALSE)
multispml.mle(x, ina, tol = 1e-07, ell = FALSE)
```

Arguments

X	A numerical vector with the circular data. They must be expressed in radians. For the "spml.mle" this can also be a matrix with two columns, the cosinus and the sinus of the circular data.
ina	A numerical vector with discrete numbers starting from 1, i.e. 1, 2, 3, 4, or a factor variable. Each number denotes a sample or group. If you supply a continuous valued vector the function will obviously provide wrong results.
tol	The tolerance level to stop the iterative process of finding the MLEs.
ell	Do you want the log-likelihood returned? The default value is FALSE.

Details

The parameters of the von Mises and of the bivariate angular Gaussian distributions are estimated for multiple samples.

Value

A list including:

iters	The iterations required until convergence. This is returned in the wrapped Cauchy distribution only.
loglik	A vector with the value of the maximised log-likelihood for each sample.
mi	For the von Mises, this is a vector with the means of each sample. For the angular Gaussian (spml), a matrix with the mean vector of each sample
ki	A vector with the concentration parameter of the von Mises distribution at each sample.
gi	A vector with the norm of the mean vector of the angular Gaussian distribution at each sample.

MLE of some truncated distributions

MLE of some truncated distributions

Description

MLE of some truncated distributions.

Usage

```
trunccauchy.mle(x, a, b, tol = 1e-07)
truncexpmle(x, b, tol = 1e-07)
```

Arguments

X	A numerical vector with continuous data. For the Cauchy distribution, they can be anywhere on the real line. For the exponential distribution they must be strictly positive.
a	The lower value at which the Cauchy distribution is truncated.
b	The upper value at which the Cauchy or the exponential distribution is truncated. For the exponential this must be greater than zero.
tol	The tolerance value to terminate the fitting algorithm.

Details

Maximum likelihood of some truncated distributions is performed.

Value

A list including:

iters The number of iterations reuired by the Newton-Raphson algorithm.

loglik The log-likelihood.

lambda The λ parameter in the exponential distribution.

param The location and scale parameters in the Cauchy distribution.

Author(s)

purka.mle
```

Examples

```
x <- rnorm(500)
trunccauchy.mle(x, -1, 1)</pre>
```

Description

MLE of the Cauchy and generalised normal distributions with zero location.

Usage

```
cauchy0.mle(x, tol = 1e-07)
gnormal0.mle(x, tol = 1e-06)
```

Arguments

x A numerical vector with positive real numbers.

tol The tolerance level up to which the maximisation stops set to 1e-07 by default.

Details

The Cauchy is the t distribution with 1 degree of freedom. The cauchy0.mle estimates the usual Cauchy distribution, over the real line, but assumes a zero location. The gnormal0.mle estimates the generalised normal distribution assuming a zero location. The generalised normal distribution is also known as the exponential power distribution or the generalized error distribution.

Value

A list including:

iters	The number of iterations required	d by the Newton-Raphson algorithm.

loglik The value of the maximised log-likelihood.

scale The estimated scale parameter of the Cauchy distribution.

param The estimated scale and shape parameters of the generalised normal distribution.

MLE of the censored Weibull distribution MLE of the censored Weibull distribution

Description

MLE of the censored Weibull distribution.

Usage

```
censweibull.mle(x, di, tol = 1e-07)
```

Arguments

di

x A vector with positive valued data (zeros are not allowed).

tol The tolerance level up to which the maximisation stops; set to 1e-07 by default.

A vector of 0s (censored) and 1s (not censored) vales.

Details

Instead of maximising the log-likelihood via a numerical optimiser we have used a Newton-Raphson algorithm which is faster.

Value

A list including:

iters The number of iterations required for the Newton-Raphson to converge.

loglik The value of the maximised log-likelihood.

param The vector of the parameters.

MLE of the gamma-Poisson distribution

MLE of the gamma-Poisson distribution

Description

MLE of the gamma-Poisson distribution.

Usage

```
gammapois.mle(x, tol = 1e-07)
```

Arguments

x A numerical vector with positive data and zeros.

tol The tolerance value to terminate the Newton-Raphson algorithm.

Details

MLE of the gamma-Poisson distribution is fitted. When the rate in the Poisson follows a gamma distribution with shape = r and scale θ , the resulting distribution is the gamm-Poisson. If the shape r is integer, the distribution is called negative binomial distribution.

Value

A list including:

iters The iterations required by the Newton-Raphson to estimate the parameters of

the distribution for the non zero data.

loglik The full log-likelihood of the model.

param The parameters of the model.

MLE of the left censored Poisson distribution

MLE of the left censored Poisson distribution

Description

MLE of the left censored Poisson distribution.

Usage

```
censpois.mle(x, tol = 1e-07)
```

Arguments

x A vector with positive valued data (zeros are not allowed).

tol The tolerance level up to which the maximisation stops; set to 1e-07 by default.

Details

Instead of maximising the log-likelihood via a numerical optimiser we have used a Newton-Raphson algorithm which is faster. The lowest value in x is taken as the censored point. Values below are censored.

Value

A list including:

iters The number of iterations required for the Newton-Raphson to converge.

loglik The value of the maximised log-likelihood.

lambda The estimated λ parameter.

```

Moran's I measure of spatial autocorrelation

Moran's I measure of spatial autocorrelation

Description

Moran's I measure of spatial autocorrelation.

Usage

```
moranI(x, w, scaled = FALSE, R = 999)
```

Arguments

X	A numerical vector with observations.
W	The inverse of a (symmetric) distance matrix. After computing the distance matrix, you invert all its elements and the elements which are zero (diagonal) and have become Inf. set them to 0. This is the w matrix the functions requires. If you want an extra step, you can row standardise this matrix by dividing each row by its total. This will make the rowsums equal to 1.
scaled	If the matrix is row-standardised (all rowsums are equal to 1) then this is TRUE and FALSE otherwise.
R	The number of permutations to use in order to obtain the permutation based-pvalue. If R is 1 or less no permutation p-value is returned.

Details

Moran' I index is a measure of spatial autocorrelation. that was proposed in 1950. Instead of computing an asymptotic p-value we compute a permutation based p-value utilizing the fast method of Chatzipantsiou et al. (2019).

Value

A vector of two values, the Moran's I index and its permutation based p-value. If R is 1 or less no permutation p-value is returned, and the second element is "NA".

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```
Naive Bayes classifier for binary (Bernoulli) data Naive\ Bayes\ classifier\ for\ binary\ Bernoulli\ data
```

Description

Naive Bayes classifier for binary (Bernoulli) data.

Usage

```
bernoulli.nb(xnew = NULL, x, ina)
```

Arguments

xnew	A numerical matrix with new predictor variables whose group is to be predicted. Each column contains binary (0 or 1) data.
x	A numerical matrix with observed predictor variables. Each column contains binary (0 or 1) data.
ina	A numerical vector with strictly positive numbers, i.e. 1,2,3 indicating the groups of the dataset. Alternatively this can be a factor variable.

Details

Each column is supposed to contain binary data. Thus, for each column a Berboulli distributions is fitted. The product of the densities is the joint multivariate distribution.

Value

A list including:

pi A matrix with the estimated probabilities of each group and variable.

ni The sample size of each group in the dataset.

est The estimated group of the xnew observations. It returns a numerical value back

regardless of the target variable being numerical as well or factor. Hence, it is suggested that you do \"as.numeric(ina)\" in order to see what is the predicted

class of the new data.

```

Naive Bayes classifiers

Naive Bayes classifiers

Description

Naive Bayes classifiers.

Usage

```
weibull.nb(xnew = NULL, x, ina, tol = 1e-07)
normlog.nb(xnew = NULL, x, ina)
laplace.nb(xnew = NULL, x, ina)
logitnorm.nb(xnew = NULL, x, ina)
beta.nb(xnew = NULL, x, ina)
cauchy.nb(xnew = NULL, x, ina)
```

Naive Bayes classifiers 101

Arguments

xnew A numerical matrix with new predictor variables whose group is to be predicted.

This is set to NUUL, as you might want just the model and not to predict the membership of new observations. For the normlog this contains positive numbers (greater than or equal to zero), but for the multinomial and Poisson cases, the matrix must contain integer valued numbers only. For the logistic normal (logitnorm.nb) and beta (beta.nb) the data must be strictly between 0 and 1.

x A numerical matrix with the observed predictor variable values. For the Gaus-

sian case (normlognb.nb) this contains positive numbers (greater than or equal to zero), but for the multinomial and Poisson cases, the matrix must contain integer valued numbers only. For the logistic normal (logitnorm.nb) and beta (beta.nb)

the data must be strictly between 0 and 1.

ina A numerical vector with strictly positive numbers, i.e. 1,2,3 indicating the

groups of the dataset. Alternatively this can be a factor variable.

tol The tolerance value to terminate the Newton-Raphson algorithm in the Weibull

distribution.

Value

Depending on the classifier a list including (the ni and est are common for all classifiers):

shape A matrix with the shape parameters.

scale A matrix with the scale parameters.

expmu A matrix with the mean parameters.

sigma A matrix with the (MLE, hence biased) variance parameters.

location A matrix with the location parameters (medians).

scale A matrix with the scale parameters.

Mean A matrix with the scale parameters.

A matrix with the variance parameters.

A matrix with the "alpha" parameters.

A matrix with the "beta" parameters.

ni The sample size of each group in the dataset.

est The estimated group of the xnew observations. It returns a numerical value back

regardless of the target variable being numerical as well or factor. Hence, it is suggested that you do \"as.numeric(ina)\" in order to see what is the predicted

class of the new data.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```

Naive Bayes classifiers for circular data

Naive Bayes classifiers for directional data

Description

Naive Bayes classifiers for directional data.

Usage

```
vm.nb(xnew = NULL, x, ina, tol = 1e-07)
spml.nb(xnew = NULL, x, ina, tol = 1e-07)
```

Arguments

xnew	A numerical matrix with new predictor variables whose group is to be predicted. Each column refers to an angular variable.
X	A numerical matrix with observed predictor variables. Each column refers to an angular variable.
ina	A numerical vector with strictly positive numbers, i.e. 1,2,3 indicating the groups of the dataset. Alternatively this can be a factor variable.
tol	The tolerance value to terminate the Newton-Raphson algorithm.

Details

Each column is supposed to contain angular measurements. Thus, for each column a von Mises distribution or an circular angular Gaussian distribution is fitted. The product of the densities is the joint multivariate distribution.

Value

A list including:

mu	A matrix with the mean vectors expressed in radians.
mu1	A matrix with the first set of mean vectors.
mu2	A matrix with the second set of mean vectors.
kappa	A matrix with the kappa parameters for the vonMises distribution or with the norm of the mean vectors for the circular angular Gaussian distribution.
ni	The sample size of each group in the dataset.
est	The estimated group of the xnew observations. It returns a numerical value back regardless of the target variable being numerical as well or factor. Hence, it is suggested that you do \"as.numeric(ina)\" in order to see what is the predicted

class of the new data.

```

Negative binomial regression

Negative binomial regression

Description

Negative binomial regression.

Usage

```
negbin.reg(y, x, tol = 1e-07, maxiters = 100)
```

Arguments

y The dependent variable, a numerical vector with integer valued numbers.

x A matrix or a data frame with the indendent variables.

tol The tolerance value required by the Newton-Raphson to stop.

maxiters The maximum iterations allowed.

Details

A negative binomial regression model is fitted. The standard errors of the regressions are not returned as we do not compute the full Hessian matrix at each step of the Newton-Raphson.

Value

A list including:

be The regression coefficients.

loglik The loglikelihood of the regression model.

iters The iterations required by the Newton-Raphson.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Stefanos Fafalios <stefanosfafalios@gmail.com>.

```

Non linear least squares regression for percentages or proportions $Non\ linear\ least\ squares\ regression\ for\ percentages\ or\ proportions$

Description

Non linear least squares regression for percentages or proportions.

Usage

```
propols.reg(y, x, cov = FALSE, tol = 1e-07 ,maxiters = 100)
```

Arguments

У	The dependent variable, a numerical vector with percentages or proporions, including 0s and or 1s.
x	A matrix with the indendent variables.
cov	Should the sandwich covariance matrix and the standard errors be returned? If yes, set this equal to TRUE.
tol	The tolerance value to terminate the Newton-Raphson algorithm. This is set to 10^{-7} by default.
maxiters	The maximum number of iterations that can take place during the fitting.

Details

The ordinary least squares between the observed and the fitted percentages is adopted as the objective function. This involves numerical optimization since the relationship is non-linear. There is no log-likelihood. This is the univariate version of the OLS regression for compositional data mentioned in Murteira and Ramalho (2016).

Value

A list including:

sse The sum of squares of the raw residuals.

be The beta coefficients.

seb The sandwich standard errors of the beta coefficients, if the input argument ar-

gument was set to TRUE.

covb The sandwich covariance matrix of the beta coefficients, if the input argument

argument was set to TRUE.

iters The number of iterations required by the Newton-Raphson algorithm.

One sample bootstrap t-test for a vector

One sample bootstrap t-test for a vector
```

Description

One sample bootstrap t-test for a vector.

Usage

```
boot.ttest1(x, m, R = 999)
```

Arguments

X	A numerical	vector with	the data.

m The assumed mean value.

R The number of bootstrap resamples to draw.

Details

The usual one sample bootstrap t-test is implemented, only faster.

Value

res

A two valued vector with the test statistic and its p-value.

Orthogonal matching pursuit variable selection

Orthogonal matching variable selection

Description

Orthogonal matching variable selection.

Usage

```
omp2(y, x, xstand = TRUE, tol = qchisq(0.95, 1), type = "gamma")
```

Arguments

у	The response variable, a numeric vector. For "omp" this can be either a vector with discrete (count) data, 0 and 1, non negative values, strictly positive or a factor (categorical) variable.
X	A matrix with the data, where the rows denote the observations and the columns are the variables.
xstand	If this is TRUE the independent variables are standardised.
tol	The tolerance value to terminate the algorithm. This is the change in the criterion value between two successive steps. For "ompr" the default value is 2 because the default method is "BIC". The default value is the 95% quantile of the χ^2 distribution.
type	This denotes the parametric model to be used each time. It depends upon the nature of y. The possible values are "gamma", "negbin", or "multinomial".

Details

This is the continuation of the "omp" function of the Rfast. We added some more regression models. The "gamma" and the "multinomial" models have now been implemented in C++.

Value

A list including:

runtime The runtime of the algorithm.

info A matrix with two columns. The selected variable(s) and the criterion value at

every step.

Parametric bootstrap for linear regression model

Parametric bootstrap for linear regression model

Description

Parametric bootstrap for linear regression model.

Usage

```
lm.parboot(x, y, R = 1000)
```

Arguments

- x The predictor variables, a vector or a matrix or a data frame.
- y The response variable, a numerical vector with data.
- R The number of parametric bootstrap replications to perform.

Details

An efficient implementation of the parametric bootstrap for linear models is provided.

Value

A matrix with R columns and rows equal to the number of the regression parameters. Each column contains the set of a bootstrap beta regression coefficients.

Permutation t-test for 2 independent samples

Permutation t-test for 2 independent samples

Description

Permutation t-test for 2 independent samples.

Usage

```
perm.ttest2(x, y, B = 999)
```

Arguments

x A numerical vector with the data.
 y A numerical vector with the data.
 B The number of permutations to perform.

Details

The usual permutation based p-value is computed.

Value

A vector with the test statistic and the permutation based p-value.

Prediction with naive Bayes classifier for binary (Bernoulli) data

Prediction with naive Bayes classifier for binary (Bernoulli) data

Description

Prediction with naive Bayes classifier for binary (Bernoulli) data.

Usage

```
bernoullinb.pred(xnew, pi, ni)
```

Arguments

xnew	A numerical matrix with new predictor variables whose group is to be predicted.
	Each column refers to an angular variable.
pi	A matrix with the estimated probabilities of each group.
ni	The sample size of each group in the dataset.

Details

Each column is supposed to contain binary data. Thus, for each column a Berboulli distributions is fitted. The product of the densities is the joint multivariate distribution.

Value

A numerical vector with 1, 2, ... denoting the predicted group.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```

Prediction with some naive Bayes classifiers

Prediction with some naive Bayes classifiers

Description

Prediction with some naive Bayes classifiers.

Usage

```
weibullnb.pred(xnew, shape, scale, ni)
normlognb.pred(xnew, expmu, sigma, ni)
laplacenb.pred(xnew, location, scale, ni)
logitnormnb.pred(xnew, m, s, ni)
betanb.pred(xnew, a, b, ni)
cauchynb.pred(xnew, location, scale, ni)
```

xnew	A numerical matrix with new predictor variables whose group is to be predicted. For the Gaussian naive Bayes, this is set to NUUL, as you might want just the model and not to predict the membership of new observations. For the Gaussian case this contains positive numbers (greater than or equal to zero), but for the multinomial and Poisson cases, the matrix must contain integer valued numbers only. For the logistic normal (logitnormnb.pred) the data must be percentages strictly between 0 and 1.
shape	A matrix with the group shape parameters. Each row corresponds to a group.
scale	A matrix with the group scale parameters of the Laplace or the Cauchy distribution. Each row corresponds to a group.
expmu	A matrix with the group mean parameters. Each row corresponds to a group.
m	A matrix with the group mean parameters. Each row corresponds to a group.
sigma	A matrix with the group (MLE, hence biased) variance parameters. Each row corresponds to a group.
S	A matrix with the group MLE variance parameters. Each row corresponds to a group.
location	A matrix with the group location parameters of the Laplace or of the Cauchy distribution. Each row corresponds to a group.
а	A matrix with the group "alpha" parameters of the beta distribution. Each row corresponds to a group.

b A matrix with the group "beta" parameters of the beta distribution. Each row corresponds to a group.

ni A vector with the frequencies of each group.

Value

A numerical vector with 1, 2, ... denoting the predicted group.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```

Prediction with some naive Bayes classifiers for circular data $Prediction \ with \ some \ naive \ Bayes \ classifiers \ for \ circular \ data$

Description

Prediction with some naive Bayes classifiers for circular data.

Usage

```
vmnb.pred(xnew, mu, kappa, ni)
spmlnb.pred(xnew, mu1, mu2, ni)
```

xnew	A numerical matrix with new predictor variables whose group is to be predicted. Each column refers to an angular variable.
mu	A matrix with the mean vectors expressed in radians.
mu1	A matrix with the first set of mean vectors.
mu2	A matrix with the second set of mean vectors.
kappa	A matrix with the kappa parameters for the vonMises distribution or with the norm of the mean vectors for the circular angular Gaussian distribution.
ni	The sample size of each group in the dataset.

Details

Each column is supposed to contain angular measurements. Thus, for each column a von Mises distribution or an circular angular Gaussian distribution is fitted. The product of the densities is the joint multivariate distribution.

Value

A numerical vector with 1, 2, ... denoting the predicted group.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```

Principal component analysis

Principal component analysis

Description

Principal component analysis.

Usage

```
pca(x, center = TRUE, scale = TRUE, k = NULL, vectors = FALSE)
```

х	A numerical $n \times p$ matrix with data where the rows are the observations and the columns are the variables.
center	Do you want your data centered? TRUE or FALSE.
scale	Do you want each of your variables scaled, i.e. to have unit variance? TRUE or FALSE.
k	If you want a specific number of eigenvalues and eigenvectors set it here, otherwise all eigenvalues (and eigenvectors if requested) will be returned.
vectors	Do you want the eigenvectors be returned? By dafault this is FALSE.

Details

The function is a faster version of R's prcomp.

Value

A list including:

values The eigenvalues. vectors The eigenvectors.

```

Principal components regression

Principal components regression

Description

Principal components regression.

Usage

```
pcr(y, x, k = 1, xnew = NULL)
```

Arguments

y A real values vector.

x A matrix with the predictor variable(s), they have to be continuous.

k The number of principal components to use. This can be a single number or a

vector starting from 1. In the second case you get results for the sequence of

principal components.

xnew If you have new data use it, otherwise leave it NULL.

Details

The principal components of the cross product of the independent variables are obtained and classical regression is performed.

Value

A list including:

be The beta coefficients of the predictor variables computed via the principcal com-

ponents.

per The percentage of variance of the cross product of the independent variables

explained by the k components.

vec The principal components, the loadings.

est The fitted or the predicted values (if xnew is not NULL).

```

Random effects meta analysis

Random effects meta analysis

Description

Random effects meta analysis.

Usage

```
refmeta(yi, vi, tol = 1e-07)
```

Arguments

yi The observations.

vi This variances of the observations.

tol The toleranve value to terminate Brent's algorithm.

Details

Random effects estimation, via restricted maximum likelihood estimation (REML), of the common mean.

Value

A vector with many elements. The fixed effects mean estimate, the \bar{v} estimate, the I^2 , the I^2 , the Q test statistic and it's p-value, the τ^2 estimate and the random effects mean estimate.

Author(s)

Michail Tsagris.

Random integer values simulation

Random integer values simulation

Description

Random integer values simulation.

Usage

```
Sample.int(n, size = n, replace = FALSE)
Sample(x, size, replace = FALSE)
```

Arguments

x A numer	ic vector for	sampling.
-----------	---------------	-----------

n This must be an integer value. The function will then draw random integer

values from 1:n.

size The number of integer values to sample.

replace Do you want to sample with replacement? If yes, set this equal to TRUE.

Details

The function does the same job, up to some level, with R's built-in fuction sample.int.

Value

A vector with integer values.

Random values simulation from the uniform distribution

Random values simulation from the uniform distribution

Description

Random values simulation from the uniform distribution.

Usage

```
Runif(n, min = 0, max = 1)
```

Arguments

n The number of values to generate.

min The lower value of the uniform distribution.

max The upper value of the uniform distribution.

Details

This function does the same job as R's built-in function runif.

Value

A vector with simulated values.

Author(s)

Manos Papadakis.

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

Regularised maximum likelihood linear discriminant analysis

Regularised maximum likelihood linear discriminant analysis

Description

Regularised maximum likelihood linear discriminant analysis.

Usage

```
reg.mle.lda(xnew, x, ina, lambda)
```

Arguments

xnew A numerical vector or a matrix with the new observations, continuous data.

x A matrix with numerical data.

ina A numerical vector or factor with consecutive numbers indicating the group to

which each observation belongs to.

lambda A vector of regularization values λ such as (0, 0.1, 0.2,...).

Details

Regularised maximum likelihood linear discriminant analysis is performed. The function is not extremely fast, yet is pretty fast.

Value

A matrix with the predicted group of each observation in "xnew". Every column corresponds to a λ value. If you have just on value of λ , then you will have one column only.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

ina <- iris[, 5]
a <- reg.mle.lda(x, x, ina, lambda = seq(0, 1, by = 0.1) )</pre>
```

Repeated measures ANOVA (univariate data) using Hotelling's T2 test Repeated measures ANOVA (univariate data) using Hotelling's T^2 test

Description

Repeated measures ANOVA (univariate data) using Hotelling's T^2 test.

Usage

```
rm.hotel(x, a = 0.05)
```

Arguments

x A numerical matrix with the repeated measurements. Each column contains the values of the repeated measurements.

The level of significance, default value is equal to 0.05.

Details

а

This is a multivariate test for the equality of means of repeated measurements.

Value

A list including:

The mean vector.

result A vector with the test statistic value, it's associated p-value, the numerator and

denominator degrees of freedom and the critical value.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```
sp.logiregs,pc.sel
```

Examples

```
x \leftarrow as.matrix(iris[, 1:4]) ## assume they are repeated measurements rm.hotel(x)
```

Sample quantiles and col/row wise quantiles

Sample quantiles and col/row wise quantiles

Description

Sample quantiles and col/row wise quantiles.

Usage

```
colQuantile(x,probs,parallel=FALSE)
## S3 method for class 'matrix'
colQuantile(x,probs,parallel=FALSE)
## S3 method for class 'data.frame'
colQuantile(x,probs,parallel=FALSE)
rowQuantile(x,probs,parallel=FALSE)
Quantile(x,probs)
```

Arguments

X	Numeric vector whose sample quantiles are wanted. NA and NaN values are not allowed in numeric vectors. For the col/row versions a numerical matrix.
probs	Numeric vector of probabilities with values in [0,1], not missing values. Values up to 2e-14 outside that range are accepted and automatically moved to the nearby endpoint by C++.
parallel	Do you want to do it in parallel, for column - row major, in C++? TRUE or FALSE.

Details

This is the same function as R's built in "quantile" with its default option, type = 7. We have also implemented it in a col/row-wise fashion.

Value

The function will return a vector of the same mode as the arguments given. NAs will be removed.

Author(s)

Manos Papadakis.

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

See Also

```

```

Examples

```
x<-rnorm(1000)
probs<-runif(10)
sum( quantile(x, probs = probs) - Quantile(x, probs) )</pre>
```

Scaled logistic regression

Scaled logistic regression

Description

Scaled logistic regression.

Usage

```
sclr(y, x, full = FALSE, tol = 1e-07, maxiters = 100)
```

У	The dependent variable; a numerical vector with two values (0 and 1).
X	A matrix with the data, where the rows denote the samples (and the two groups) and the columns are the variables. This can be a matrix or a data.frame (with factors).
full	If this is FALSE, the coefficients and the log-likelihood will be returned only. If this is TRUE, more information is returned.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
maxiters	The max number of iterations that can take place in each regression.

Value

When full is FALSE a list including:

theta The estimated *theta* parameter.

be The estimated regression coefficients.

loglik The log-likelihood of the model.

iters The number of iterations required by Newton-Raphson.

When full is TRUE a list including:

info The estimated theta, regression coefficients, their standard error, their Wald test

statistic and their p-value.

loglik The log-likelihood.

iters The number of iterations required by Newton-Raphson.

Score test for overdispersion in Poisson regression

Score test for overdispersion in Poisson regression

Description

Score test for overdispersion in Poisson regression.

Usage

```
overdispreg.test(y, x)
```

Arguments

y A vector with count data.

x A numerical matrix with predictor variables.

Details

A score test for overdispersion in Poisson regression is implemented.

Value

A vector with two values. The test statistic and its associated p-value.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

References

Yang Z., Hardin J.W. and Addy C.L. (2009). A score test for overdierpsdion in Poisson regression based on the generalised Poisson-2 model. Journal of Statistical Planning and Inference, 139(4): 1514–1521.

Single terms deletion hypothesis testing in a linear regression model ${\it Single \ terms \ deletion \ hypothesis \ testing \ in \ a \ linear \ regression \ model}}$

Description

Single terms deletion hypothesis testing in a linear regression model.

Usage

```
lm.drop1(y, x, type = "F")
```

Arguments

У	The dependent variable, a numerical vector with numbers.
X	A numerical matrix with the indendent variables. We add, internally, the first column of ones.
type	If you want to perform the usual F (or t) test set this equal to "F". For the test based on the partial correlation set this equal to "cor".

Details

This is the same function as R's built in drop1 that it works with the F test or the partial correlation coefficient. For the linear regression model, the Wald test is equivalent to the partial F test. So, instead of performing many regression models with single term deletions we perform one regression model with all variables and compute their Wald test effectively. Note, that this is true, only if the design matrix "x" contains the vectors of ones and in our case this must be, strictly, the first column. The second option is to compute the p-value of the partial correlation.

Value

A matrix with two columns. The test statistic and its associated pvalue for each independent variable.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

drop1(a, test = "F")
lm.drop1(y, x )</pre>
```

Skeleton of the FEDHC algorithm

The skeleton of a Bayesian network produced by the FEDHC algorithm

Description

The skeleton of a Bayesian network produced by the FEDHC algorithm.

Usage

```
fedhc.skel(x, method = "pearson", alpha = 0.05,
ini.stat = NULL, R = NULL, parallel = FALSE)
```

Arguments

х	A numerical matrix with the variables. If you have a data.frame (i.e. categorical data) turn them into a matrix using data.frame.to_matrix from the R package Rfast . Note, that for the categorical case data, the numbers must start from 0. No missing data are allowed.
method	If you have continuous data, this "pearson". If you have categorical data though, this must be "cat". In this case, make sure the minimum value of each variable is zero. The function "g2Test" in the R package Rfast and the relevant functions work that way.
alpha	The significance level (suitable values in $(0, 1)$) for assessing the p-values. Default value is 0.05 .
ini.stat	If the initial test statistics (univariate associations) are available, pass them through this parameter.
R	If the correlation matrix is available, pass it here.
parallel	Set this to TRUE for parallel computations.

Details

Similar to MMHC and PCHC the first phase consists of a variable selection procedure, the FBED algorithm (Borboudakis and Tsamardinos, 2019).

Value

A list including:

ini.stat The test statistics of the univariate associations.

The initial p-values univariate associations.

pvalue A matrix with the logarithm of the p-values of the updated associations. This final p-value is the maximum p-value among the two p-values in the end.

runtime The duration of the algorithm.

ntests The number of tests conducted during each k.

G The adjancency matrix. A value of 1 in G[i, j] appears in G[j, i] also, indicating

that i and j have an edge between them.

Author(s)

Michail Tsagris and Stefanos Fafalios.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Stefanos Fafalios <stefanosfafalios@gmail.com>.

# simulate a dataset with continuous data
x <- matrix( rnorm(200 * 50, 1, 10), nrow = 200 )
a <- fedhc.skel(x)</pre>
```

Skeleton of the MMHC algorithm

The skeleton of a Bayesian network learned with the MMHC algorithm

Description

The skeleton of a Bayesian network learned with the MMHC algorithm.

Usage

```
mmhc.skel(x, method = "pearson", max_k = 3, alpha = 0.05,
ini.stat = NULL, R = NULL, parallel = FALSE)
```

Arguments

A numerical matrix with the variables. If you have a data.frame (i.e. categorical Χ data) turn them into a matrix using data. frame.to_matrix from the R package Rfast. Note, that for the categorical case data, the numbers must start from 0. No missing data are allowed. method If you have continuous data, this "pearson". If you have categorical data though, this must be "cat". In this case, make sure the minimum value of each variable is zero. The function "g2Test" in the R package Rfast and the relevant functions work that way. The maximum conditioning set to use in the conditional indepedence test (see max_k Details). Integer, default value is 3. alpha The significance level (suitable values in (0, 1)) for assessing the p-values. Default value is 0.05. ini.stat If the initial test statistics (univariate associations) are available, pass them through this parameter. R If the correlation matrix is available, pass it here. parallel Set this to TRUE for parallel computations.

Details

The max_k option: the maximum size of the conditioning set to use in the conditioning independence test. Larger values provide more accurate results, at the cost of higher computational times. When the sample size is small (e.g., < 50 observations) the max_k parameter should be 3 for example, otherwise the conditional independence test may not be able to provide reliable results.

Value

A list including:

ini.stat The test statistics of the univariate associations.
ini.pvalue The initial p-values univariate associations.

pvalue A matrix with the logarithm of the p-values of the updated associations. This

final p-value is the maximum p-value among the two p-values in the end.

runtime The duration of the algorithm.

ntests The number of tests conducted during each k.

G The adjancency matrix. A value of 1 in G[i, j] appears in G[j, i] also, indicating

that i and j have an edge between them.

Split the matrix in lower, upper triangular and diagonal

Split the matrix in lower, upper triangular and diagonal
```

Description

Split the matrix in lower, upper triangular and diagonal.

Usage

lud(x)

Arguments

A matrix with data.

Value

A list with 3 fields:

lower The lower triangular of argument "x".

The upper triangular of argument "x".

diagonal The diagonal elements.

The k-NN algorithm for really lage scale data

The k-NN algorithm for really lage scale data

Description

The k-NN algorithm for really lage scale data.

Usage

```
big.knn(xnew, y, x, k = 2:100, type = "C")
```

Arguments

xnew	A matrix with new data, new predictor variables whose response variable must be predicted.
У	A vector of data. The response variable, which can be either continuous or categorical (factor is acceptable).
Χ	A matrix with the available data, the predictor variables.
k	A vector with the possible numbers of nearest neighbours to be considered.
type	If your response variable y is numerical data, then this should be "R" (regression). If y is in general categorical set this argument to "C" (classification).

Details

The concept behind k-NN is simple. Suppose we have a matrix with predictor variables and a vector with the response variable (numerical or categorical). When a new vector with observations (predictor variables) is available, its corresponding response value, numerical or categorical, is to be predicted. Instead of using a model, parametric or not, one can use this ad hoc algorithm.

The k smallest distances between the new predictor variables and the existing ones are calculated. In the case of regression, the average, median, or harmonic mean of the corresponding response values of these closest predictor values are calculated. In the case of classification, i.e. categorical response value, a voting rule is applied. The most frequent group (response value) is where the new observation is to be allocated.

This function allows for the Euclidean distance only.

Tobit regression 131

Value

A matrix whose number of columns is equal to the size of k. If in the input you provided there is just one value of k, then a matrix with one column is returned containing the predicted values. If more than one value was supplied, the matrix will contain the predicted values for every value of k.

Tobit regression

Tobit regression

Description

Tobit regression.

Usage

```
tobit.reg(y, x, ylow = 0, full = FALSE, tol = 1e-07, maxiters = 100)
```

у	The dependent variable; a numerical vector with values.
X	A matrix with the data, where the rows denote the samples (and the two groups) and the columns are the variables. This can be a matrix or a data.frame (with factors).
ylow	The lowest value below which nothing is observed. The cut-off value.
full	If this is FALSE, the coefficients and the log-likelihood will be returned only. If this is TRUE, more information is returned.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
maxiters	The max number of iterations that can take place in each regression.
tol	this is TRUE, more information is returned. The tolerance value to terminate the Newton-Raphson algorithm.

Tobit regression

Details

The tobit regression model is fitted.

Value

When full is FALSE a list including:

be The estimated regression coefficients.

s The estimated scale parameter.

loglik The log-likelihood of the model.

iters The number of iterations required by Newton-Raphson.

When full is TRUE a list including:

info The estimated theta, regression coefficients, their standard error, their Wald test

statistic and their p-value.

loglik The log-likelihood.

iters The number of iterations required by Newton-Raphson.

Trimmed mean 133

Trimmed mean	
--------------	--

Description

Trimmed mean.

Usage

```
trim.mean(x, a = 0.05)
colTrimMean(x, a = 0.05,parallel=FALSE)
## S3 method for class 'matrix'
colTrimMean(x,a = 0.05,parallel=FALSE)
## S3 method for class 'data.frame'
colTrimMean(x,a = 0.05,parallel=FALSE)
rowTrimMean(x, a = 0.05,parallel=FALSE)
```

Arguments

x A numerical vector or a numerical matrix.

a A number in (0, 1), the proportion of data to trim.

parallel Run the algorithm parallel in C++.

Details

The trimmed mean is computed. The lower and upper a% of the data are removed and the mean is calculated using the rest of the data.

Value

The trimmed mean.

```

Variable selection using the PC-simple algorithm $Variable \ selection \ using \ the \ PC-simple \ algorithm$

Description

Variable selection using the PC-simple algorithm.

Usage

```
pc.sel(y, x, ystand = TRUE, xstand = TRUE, alpha = 0.05)
```

Arguments

у	A numerical vector with continuous data.
X	A matrix with numerical data; the independent variables, of which some will probably be selected.
ystand	If this is TRUE the response variable is centered. The mean is subtracted from every value.
xstand	If this is TRUE the independent variables are standardised.
alpha	The significance level.

Details

Variable selection for continuous data only is performed using the PC-simple algorithm (Buhlmann, Kalisch and Maathuis, 2010). The PC algorithm used to infer the skeleton of a Bayesian Network has been adopted in the context of variable selection. In other words, the PC algorithm is used for a single node.

Value

A list including:

vars A vector with the selected variables.

n.tests The number of tests performed.

runtime The runtime of the algorithm.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

```

Wald confidence interval for the ratio of two Poisson variables

Wald confidence interval for the ratio of two Poisson variables

Description

Wald confidence interval for the ratio of two Poisson variables.

Usage

```
wald.poisrat(x, y, alpha = 0.05)
col.waldpoisrat(x, y, alpha = 0.05)
```

Arguments

x A numeric vector or a matrix with count data.
 y A numeric vector or a matrix with count data.
 alpha The 1 - confidence level. The default value is 0.05.

Details

wald confidence interval for the ratio of two Poisson means is/are calculated.

Value

For the wald.poisrat a vector with three elements, the ratio and the lower and upper confidence interval limits. For the col.waldpoisrat a matrix with three columns, the ratio and the lower and upper confidence interval limits.

```

Walter's confidence interval for the ratio of two binomial variables (and the relative risk)

Walter's confidence interval for the ratio of two binomial variables

(and the relative risk)

Description

Walter's confidence interval for the ratio of two binomial variables (and the relative risk).

Usage

```
walter.ci(x1, x2, n1, n2, a = 0.05)
```

Arguments

x1	An integer number, greater than or equal to zero.
x2	A secondinteger number, greater than or equal to zero.
n1	An integer number, greater than or x1.
n2	A secondinteger number, greater than or equal to x2.
a	The significance level. The produced confidence interval has a confidence level equal to 1-a.

Details

This calculates a (1-a)% confidence interval for the ratio of two binomial variables (and hence for the relative risk) using Walter's suggestion (Walter, 1975). That is, to add 0.5 in each number. This not only overcomes the problem of zero values, but produces intervals that are more accurate than the classical asymptotic confidence interval (Alharbi and Tsagris, 2018).

Value

A list including:

rat The ratio of the two binomial distributions.

ci Walter's confidence interval.

Zero inflated Gamma regression

Zero inflated Gamma regression

Description

Zero inflated Gamma regression.

Usage

```
zigamma.reg(y, x, full = FALSE, tol = 1e-07, maxiters = 100)
```

Arguments

У	The dependent variable, a numerical vector with numbers, zeros and higher.
X	A numerical matrix with the indendent variables. We add, internally, the first column of ones.
full	If this is FALSE, the coefficients and the log-likelihood will be returned only. If this is TRUE, more information is returned.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
maxiters	The maximum number of iterations that can take place in each regression.

Details

Two regression models are fitted, a binary logistic regression and a Gamma regression model to the non-zero responses.

Value

Depending on whether "full" is TRUE or not different outputs are returned. In general, the regression coefficients, the iterations required by Newton-Raphson and the deviances are returned. If full is TRUE, a matrix with their standard errors and the Wald test statistics is returned as well.

```

Zero truncated Poisson regression

Zero truncated Poisson regression

Description

Zero truncated Poisson regression.

Usage

```
ztp.reg(y, x, full = FALSE, tol = 1e-07, maxiters = 100)
```

Arguments

y The dependent variable, a numerical vector with integer valued numbers.

x A matrix or a data frame with the indendent variables.

full If you want full information (standard errors, Walt test statistics and p-values of

the regression coefficients) set this equal to TRUE.

tol The tolerance value required by the Newton-Raphson to stop.

maxiters The maximum iterations allowed.

Details

A zero truncated poisson regression model is fitted.

Value

A list including:

be The regression coefficients if "full" was set to FALSE.

info This is returned only if "full" was set to TRUE. It is a matrix with the regression

coefficients, their standard errors, Walt test statistics and p-values.

loglik The loglikelihood of the regression model.

iter The iterations required by the Newton-Raphson.
