Type Package

Title Functional Singular Spectrum Analysis

Version 2.0.1

Maintainer Hossein Haghbin <haghbinh@gmail.com>

URL <https://github.com/haghbinh/Rfssa>

Description Methods and tools for implementing univariate and multivariate functional singular spectrum analysis for functional time series whose variables might be observed over different dimensional domains. The univariate fssa algorithm is described in Haghbin H., Najibi, S.M., Mahmoudvand R., Trinka J., Maadooliat M. (2021) and the multivariate fssa over different dimensional domains technique may be found in Trinka J., Haghbin H., and Maadooliat M. (Accepted). In addition, one may perform forecasting of univariate and multivariate fts whose variables are observed over one-dimensional domains as described in the dissertation of Trinka J. (2021) and the manuscript of Trinka J., Haghbin H., Maadooliat M. (2020) where the manuscript is to be submitted to a journal for publication.

`*.fts` *Multiplication of Functional Time Series*

Description

A method for functional time series ([fts](#)) pointwise multiplication and fts-scalar multiplication. Note that if the fts is multivariate then a vector of numerics may be provided allowing for multiplication of different variables by different scalars. For example, multivariate fts-numeric multiplication follows the form of `Y*c(1,2)` if `Y` is a bivariate fts.

Usage

```
## S3 method for class 'fts'
Y1 * Y2
```

Arguments

Y1	An object of class [fts](#) or numeric.
Y2	An object of class [fts](#) or numeric.

Value

An object of class [fts](#).

See Also

fts

Examples

```
## Not run:
require(Rfssa)
load_github_data("https://github.com/haghbinh/Rfssa/blob/master/data/Callcenter.RData")
D <- matrix(sqrt(Callcenter$calls), nrow = 240)
u <- seq(0, 1, length.out = 240) # Define domain of functional data
d <- 22 # number of basis elements
Y <- fts(list(D), list(list(d, "bspline")), list(u))
plot(Y)
Ytimes <- Y * Y # multiply the functional time series by itself
plot(Ytimes)
Ytimes2 <- Y * 2 # multiply every term in the fts by 2
plot(Ytimes2)

## End(Not run)
```

+.fts *Addition of Functional Time Series*

Description

A method for functional time series (fts) addition and fts-scalar addition. Note that if the fts is multivariate then a vector of numerics may be provided allowing for addition of different scalars to different variables. For example, multivariate fts-numeric addition follows the form of Y+c(1,2) if Y is a bivariate fts.

Usage

```
## S3 method for class 'fts'
Y1 + Y2
```

Arguments

Y1	An object of class fts or numeric.
Y2	An object of class fts or numeric.

Value

An object of class fts.

See Also

fts

Examples

```
## Not run:
require(Rfssa)
load_github_data("https://github.com/haghbinh/Rfssa/blob/master/data/Callcenter.RData")
D <- matrix(sqrt(Callcenter$calls), nrow = 240)
u <- seq(0, 1, length.out = 240) # Define domain of functional data
d <- 22 # number of basis elements
Y <- fts(list(D), list(list(d, "bspline")), list(u))
plot(Y)
Yplus <- Y + Y # add the functional time series to itself
plot(Yplus)
Yplus2 <- Y + 2 # add 2 to every term in the functional time series
plot(Yplus2)

## End(Not run)
```

-.fts   *Subtraction of Functional Time Series*

Description

A method for functional time series ([fts](#)) subtraction and fts-scalar subtraction. Note that if the fts is multivariate then a vector of numerics may be provided allowing for subtraction of different scalars from different variables. For example, multivariate fts-numeric subtraction follows the form of Y-c(1,2) if Y is a bivariate fts.

Usage

```
## S3 method for class 'fts'
Y1 - Y2
```

Arguments

Y1	An object of class [fts](#) or numeric.
Y2	An object of class [fts](#) or numeric.

Value

An object of class [fts](#).

See Also

[fts](#)

Examples

```
## Not run:
require(Rfssa)
load_github_data("https://github.com/haghbinh/Rfssa/blob/master/data/Callcenter.RData")
D <- matrix(sqrt(Callcenter$calls), nrow = 240)
u <- seq(0, 1, length.out = 240) # Define domain of functional data
d <- 22 # number of basis elements
Y <- fts(list(D), list(list(d, "bspline")), list(u))
plot(Y)
Yminus <- Y[1:4] - Y[5:8] # subtract the functional time series to itself
plot(Yminus)
Yminus2 <- Y - 2 # subtract 2 to every term in the functional time series
plot(Yminus2)

## End(Not run)
```

Callcenter *Number of Calls for a Bank.*

Description

This dataset is a small call center for an anonymous bank (Brown et al., 2005). This dataset provides the exact time of the calls that were connected to the center from January 1 to December 31 in the year 1999. The data are aggregated into time intervals to obtain a data matrix. More precisely, the *(i,j)*'th element of the data matrix contains the call volume during the *j*th time interval on day *i*. This dataset has been analyzed in several prior studies; e.g. Brown et al. (2005), Shen and Huang (2005), Huang et al. (2008), and Maadooliat et al. (2015). Here, the data are aggregated into time intervals of 6 minutes. The data is hosted on GitHub and `load_github_data` may be used to load the data.

Format

A dataframe with 87600 rows and 5 variables:

calls The number of calls in 6 minutes aggregated interval.

u A numeric vector to show the aggregated interval.

Date Date time when the calls counts are recorded.

Day Weekday associated with Date.

Month Month associated with Date.

cor.fts   *Correlation for Functional Time Series Objects*

Description

This function finds the correlation between univariate or multivariate functional time series ([fts](#)) objects.

Usage

```
cor.fts(Y1, Y2)
```

Arguments

Y1   An object of class [fts](#).

Y2   An object of class [fts](#).

Value

A scalar that is the correlation between [fts](#) objects.

fforecast   *Functional Singular Spectrum Analysis Recurrent Forecasting and*
                                   Vector Forecasting

Description

This function performs functional singular spectrum analysis (FSSA) recurrent forecasting (FSSA R-forecasting) or vector forecasting (FSSA V-forecasting) of univariate or multivariate functional time series ([fts](#)) observed over a one-dimensional domain.

Usage

```
fforecast(U, groups = list(c(1)), h = 1, method = "recurrent", tol = 10^-3)
```

Arguments

U	An object of class [fssa](#) that holds the decomposition.
groups	A list of numeric vectors where each vector includes indices of elementary components of a group used for reconstruction and forecasting.
h	An integer that specifies the forecast horizon.
method	A character string specifying the type of forecasting to perform either "recurrent" or "vector".
tol	A double specifying the amount of tolerated error in the approximation of the matrix that corresponds with the operator formed using a Neumann series leveraged in both forecasting algorithms; see Trinka et. al. (2021) for more details.

Value

A list of objects of class [fts](#) where each fts corresponds to a forecasted group.

Examples

```

freconstruct	*Reconstruction Stage of Functional Singular Spectrum Analysis*

Description

This is a function for reconstructing univariate or multivariate functional time series ([fts](#)) objects from functional singular spectrum analysis ([fssa](#)) objects (including Grouping and Hankelization steps). The function performs the reconstruction step for univariate functional singular spectrum analysis (ufssa) or multivariate functional singular spectrum analysis (mfssa) depending on whether or not the input is an [fssa](#) object from ufssa or mfssa.

Usage

```
freconstruct(U, groups = as.list(1L:10L))
```

Arguments

U	An object of class [fssa](#).
groups	A list of numeric vectors, each vector includes indices of elementary components. of a group used for reconstruction.

Value

A named list of objects of class [fts](#) that are reconstructed as according to the specified groups and a numeric vector of eigenvalues.

Note

Refer to [fssa](#) for an example on how to run this function starting from [fssa](#) objects.

fssa   *Functional Singular Spectrum Analysis*

Description

This is a function which performs the decomposition (including embedding and functional SVD steps) stage for univariate functional singular spectrum analysis (ufssa) or multivariate functional singular spectrum analysis (mfssa). The algorithm (ufssa or mfssa) is chosen based on whether the supplied input is a univariate or multivariate functional time series ([fts]()) object. The type parameter can also be set to "mfssa" if the user wishes to perform ufssa of a univariate [fts]() object using the mfssa code. Also note that the variables of the [fts]() maybe observed over different dimensional domains where the maximum dimension currently supported is two.

Usage

```
fssa(Y, L = NA, ntriples = 20, type = "ufssa")
```

Arguments

Y	An object of class [fts]().
L	A positive integer giving the window length.
ntriples	A positive integer specifying the number of eigentriples to calculate in the decomposition.
type	A string indicating which type of fssa to perform. Use type="ufssa" to perform univariate fssa (default for univariate fts). Use type="mfssa" to perform multivariate fssa (default for multivariate fts).

Value

An object of class fssa, which is a list of functional objects and the following components:

values	A numeric vector of eigenvalues.
L	The specified window length.
N	The length of the functional time series.
Y	The original functional time series.

Examples

```

fts   *Functional Time Series Class*

Description

This function is used to create functional time series (fts) objects from lists of discretely sampled
data, basis specifications, and grid elements which provide the domain that each variable is observed
over. Each variable is assumed to be observed over a regular and equidistant grid. In addition, each
variable in the fts is assumed to be observed over a one or two-dimensional domain.

Usage

```
fts(X, B, grid)
```

Arguments

X
: A list of length p where p is a positive integer specifying the number of variables observed in the fts. Each entry in the list should be a matrix or an array. For a variable observed over a one-dimensional domain, the list entry should be an m by N matrix where m is the number of sampling points for each observation and N is the number of observations. For a variable observed over a two-dimensional domain, the list entry should be an m_1 by m_2 by N array where m_1 is the number of sampling points in the horizontal direction and m_2 is the number of sampling points in the vertical direction.

B
: A list of length p. Each entry in the list should be either a matrix specifying the basis for each variable or each list entry should be a list specifying the number of basis elements and desired basis type to be used in the smoothing process. For a variable observed over a one-dimensional domain, the list entry should be a m by d matrix or the list entry should be a list of the form, list(d,"basistype"), where d specifies the number basis elements and "basistype" is a string that is set to "bspline" or "fourier" to specify the type of basis. For a variable observed over a two-dimensional domain, the list entry should be a (m_1)(m_2) by (d_1)(d_2) matrix or the list entry should be a list of the form, list(d_1,d_2,"basistype1","basisty where d_1 and d_2 specify the number of basis elements in the horizontal and vertical directions respectively, and "basistype1" and "basistype2" are set to be "bspline" or "fourier" which specifies the type of basis in the horizontal direction, and "basistype2" is set to be "bspline" or "fourier" to specify the type of basis in the horizontal and vertical directions respectively.

grid
: A list of length p. Each entry in the list should either be a numeric or a list of numeric elements depending on the dimension of the domain the variable is observed over. For a variable observed over a one-dimensional domain, the list entry should be either an ordered (from smallest to largest) numeric of length m giving the sampling points or a numeric of the form, c(x_1,x_2) where x_1 and x_2 are the smallest and largest values attained in the domain of the variable respectively. In addition, these list entries can also be provided in a list. For a variable observed over a two-dimensional domain, the list entry should be either a list of the form, list(u,v), or of the form, list(c(x_1,x_2),v), or of the form, list(u,c(x_3,x_4)), or of the form, list(c(x_1,x_2),c(x_3,x_4)) where u is a numeric with minimium and maximum values of x_1 and x_2 respectively and v is a numeric with minimium and maximum values of x_3 and x_4 respectively.

Note

fwcor | *Weighted Correlation Matrix*

Description

This function returns the weighted correlation (w-correlation) matrix for functional time series ([fts](#)) objects that were reconstructed from functional singular spectrum analysis ([fssa](#)) objects.

Usage

```
fwcor(U, groups)
```

Arguments

U   An object of class [fssa](#).

groups   A list or vector of indices which determines the grouping used for the recon-
               struction in pairwise w-correlations matrix.

Value

A square matrix of w-correlation values for the reconstructed [fts](#) objects that were built from. [fssa](#) components

Jambi   *Jambi MODIS Data*

Description

This data set contains the normalized difference vegetation index (NDVI) and enhanced vegetation index (EVI) image data from NASA's MODerate-resolution Imaging Spectroradiometer (MODIS) with global coverage at 250 m^2. The goal of the study is to collect raw image data of the Jambi Province, Indonesia. Indonesia manages various forested land utilizations such as natural forest and plantations which, in the past, have been exploited throughout the country. Greater criticisms on forest exploitation lead to a moratorium which needs to be monitored frequently. Assessment of woody vegetation could be taken using field surveys or remote sensing. It was found that season is probably the most intriguing factor in vegetative land cover, especially in long-term land cover changes (Lambin, 1999). The data was gathered starting in 2000-02-18 and ending in 2019-07-28 every 16 days. The data is hosted on GitHub and `load_github_data` may be used to load the data.

Format

A list which contains two 33 by 33 by 448 arrays where one array is for NDVI image data and the other is for EVI image data. The list also contains a date vector of length 448 which specifies upon which date was each image 33 by 33 image taken.

Days 1 - 448 Pixel intensity with values between zero and one

Description

This function launches an app that can be used to help an individual better understand univariate or multivariate functional singular spectrum analysis (fssa). The app allows the user to run univariate or multivariate functional singular spectrum analysis (depending on the entered type of parameter) on a variety of data types including simulated and real data available through the server. The app also has functionality that allows the user to upload their own data. The app allows the user to compare different methods simultaneously such as multivariate singular spectrum analysis versus univariate functional singular spectrum analysis. It also allows the user to choose the number and types of basis elements used to estimate functional time series ([fts](fts)) objects. The app supports [fts](fts) plots and fssa plots.

Usage

```
launchApp(type = "ufssa")
```

Arguments

type   Type of FSSA with options of type = "ufssa" or type = "mfssa".

Value

A shiny application object.

Examples

```
## Not run:

launchApp()

## End(Not run)
```

---

load_github_data   *Load Data from GitHub Repositories*

Description

This function was found in https://stackoverflow.com/questions/24846120/importing-data-into-r-rdata-from-github and can be used to load .RData files from GitHub repositories. This function can be used to load the Callcenter, Jambi, and Montana datasets from the Rfssa package hosted by GitHub at https://github.com/haghbinh/Rfssa. It was found that hosting such datasets on GitHub and not including them in the Rfssa R package saved a significant amount of space.

Usage

```
load_github_data(github_data_url)
```

Arguments

```
github_data_url
```
> The GitHub url of the dataset.

Value

A dataset specified by a GitHub url.

Examples

```
## Not run:
# Loading different datasets from the Rfssa repository hosted by GitHub.
call <- load_github_data("https://github.com/haghbinh/Rfssa/blob/master/data/Callcenter.RData")
jambi <- load_github_data("https://github.com/haghbinh/Rfssa/blob/master/data/Jambi.RData")
montana <- load_github_data("https://github.com/haghbinh/Rfssa/blob/master/data/Montana.RData")

## End(Not run)
```

| Montana | *Montana Intraday Temperature Curves and NDVI Images Data Set* |

Description

This data set contains the intraday hourly temperature curves measured in degrees celcius and normalized difference vegetation index (NDVI) image data where both types of data are recorded near Saint Mary, Montana, USA. The NDVI images are taken of a region located between longitudes of 113.30 degrees West and 113.56 degrees west and latitudes of 48.71 degrees North and 48.78 degrees North. The intraday temperature curves are available for download from Diamond et al. (2013) and the NDVI images were attained leveraging resources provided by Tuck et al. (2014). For each recorded intraday temperature curve, an NDVI image was recorded on the same day, every 16 days, starting January 1, 2008 and ending September 30, 2013. With the the threat of global warming damaging various ecosystems, the goal of the study was to analyze trends in the temperature and to investigate how changes in temperature effects the amount of vegetation in the region. We discovered that leveraging both types of variables in a multivariate analysis revealed a stronger signal extraction result and more informative patterns. The data is hosted on GitHub and `load_github_data` may be used to load the data.

Format

A list which contains a 24 by 133 matrix of discrete samplings of intraday hourly temperature curves and an array that is 33 by 33 by 133 where one 33 by 33 slice of the array is an NDVI image.

| plot.fssa | *Plot Functional Singular Spectrum Analysis Objects* |

Description

This is a plotting method for objects of class functional singular spectrum analysis (`fssa`). The method is designed to help the user make decisions on how to do the grouping stage of univariate or multivariate functional singular spectrum analysis.

Usage

```
## S3 method for class 'fssa'
plot(
  x,
  d = length(x$values),
  idx = 1:d,
  idy = idx + 1,
  contrib = TRUE,
  groups = as.list(1:d),
  type = "values",
  vars = NULL,
  ylab = NA,
  ...
)
```

Arguments

x	An object of class [fssa](#).
d	An integer which is the number of elementary components in the plot.
idx	A vector of indices of eigen elements to plot.
idy	A second vector of indices of eigen elements to plot (for type="paired").
contrib	A logical where if the value is TRUE (the default), the contribution of the component to the total variance is displayed.
groups	A list or vector of indices determines grouping used for the decomposition(for type="wcor").
type	The type of plot to be displayed where possible types are: • "values" plot the square-root of singular values (default) • "paired" plot the pairs of eigenfunction's coefficients (useful for the detection of periodic components) • "wcor" plot the W-correlation matrix for the reconstructed objects • "vectors" plot the eigenfunction's coefficients (useful for the detection of period length) • "lcurves" plot of the eigenfunctions (useful for the detection of period length) • "lheats" heatmap plot of the eigenfunctions which can be used for [fts](#) variables observed over one or two-dimensional domains (useful for the detection of meaningful patterns) • "periodogram" periodogram plot (useful for the detecting the frequencies of oscillations in functional data).
vars	A numeric specifying the variable number (can be used in plotting MFSSA "lheats" or "lcurves").
ylab	The character vector of name of variables.
...	Arguments to be passed to methods, such as graphical parameters.

Note

See [fssa](#) examples.

plot.fts   *Functional Time Series Visualization Tools Using Plotly*

Description

This is a plotting method for univariate or multivariate functional time series ([fts](#)). This method is designed to help the user visualize [fts](#) data using a variety of techniques that use plotly.

Usage

```
## S3 method for class 'fts'
plot(
  x,
  vars = NULL,
  types = NULL,
  subplot = TRUE,
  mains = NULL,
  ylabels = NULL,
  xlabels = NULL,
  tlabels = NULL,
  zlabels = NULL,
  ...
)
```

Arguments

x	An object of class [fts](#).
vars	A numeric specifying which variables in the fts to plot. The default is to plot all variables in succession. Note as well that variable indices may be repeated.
types	A tuple of strings specifying the types of plots to be displayed where possible types for fts variables observed over a one-dimensional domain are:

- "line" plot the [fts](#) elements in a line plot (default)
- "heatmap" plot the [fts](#) elements in a heat map which can be used for variables observed over one or two-dimensional domains
- "3Dsurface" plot the [fts](#) elements as a surface
- "3Dline" plot the [fts](#) elements in a three-dimensional line plot.

The current plot type supported for fts variables observed over a two-dimensional domain is "heatmap". Also note that the same variable may be plotted several times using many different type options.

subplot	A logical specifying whether or not line plots should be plotted in a subplot or not. The default is TRUE and if any other plot type is provided, the value is switched to FALSE.
mains	A tuple of strings providing the the main titles of each plot.
ylabels	A tuple of strings providing the the y-axis titles of each plot.
xlabels	A tuple of strings providing the the x-axis titles of each plot.
tlabels	A tuple of strings providing the the time-axis titles of each plot.
zlabels	A tuple of strings providing the the z-axis titles of each plot.
...	arguments to be passed to methods, such as graphical parameters.

Note

For examples, see fssa

Rfssa	*Rfssa: A Package for Functional Singular Spectrum Analysis and Related Methods.*

Description

The Rfssa package provides the collection of necessary functions to implement functional singular spectrum analysis (FSSA)-based methods for analyzing univariate and multivariate functional time series (FTS). Univariate and multivariate FSSA are novel, non-parametric methods used to perform decomposition and reconstruction of univariate and multivariate FTS respectively. In addition, the FSSA-based routines may be performed on FTS whose variables are observed over a one or two-dimensional domain. Finally, one may perform FSSA recurrent or fssa vector forecasting of univariate or multivariate FTS observed over one-dimensional domains. Forecasting of FTS whose variables are observed over domains of dimension greater than one is under development.

Details

The use of the package starts with the decomposition of functional time series ([fts](fts)) objects using the fssa routine. Then a suitable grouping of the principal components is required for reconstruction (freconstruct) or forecasting (fforecast) which can be done heuristically by looking at the plots of the decomposition. Once a suitable grouping is chosen, one may perform reconstruction where the sum of all the elements between the disjoint groups approximates the original FTS. One may also choose to perform forecasting after a grouping is chosen which returns future observations in each FTS specified by the groups.

This version of the package leverages a new S4 object for FTS objects ([fts](fts)). Along with providing the raw, sampled data, the new object may be specified using a provided basis and grid, a requested basis and grid, or a mixture of provided and requested elements. We note that the FTS object may be univariate or multivariate and variables may be observed over one or two-dimensional domains. Validity checking of the S4 object constructor inputs was also added to help guide the user. The plotting of FTS objects was also updated to allow the user to plot FTS variables observed over two-dimensional domains. Next, the FSSA routine (fssa) was updated to perform faster by

leveraging the RSpectra and RcppEigen R packages, and the Eigen C++ package. We achieved a roughly 20 times speed up for certain data examples. We updated the plotting of fssa objects to allow for plotting of left singular functions that correspond with FTS variables observed over a two-dimensional domain. We updated FSSA reconstruction `freconstruct` to handle FTS whose variables are observed over one or two-dimensional domains. We also updated FTS arithmetic (such as FTS addition, FTS subtraction, etc.) to allow the user to perform scalar-FTS arithmetic on different variables of a multivariate FTS. In addition, we also now host the `Callcenter`, `Jambi`, and `Montana` datasets on GitHub to significantly decrease the size of the package. In order to load the data, one simply needs to use the `load_github_data` function. This same function can also be used to load data from any other public GitHub repository.

The first piece of new functionality that has been added is that the user may now specify univariate or multivariate FTS comprised of variables observed over one or two-dimensional domains. In addition, forecasting of univariate and multivariate FTS observed over one-dimensional domains by FSSA/MFSSA recurrent forecasting and FSSA/MFSSA vector forecasting has also been added. We have also added in a new data set (`Montana`) which provides the data for a multivariate FTS observed over different dimensional domains.

The package update also includes updates to the shiny app (`launchApp`) that can be used for demonstrations of univariate or multivariate FSSA depending on the type that is specified. The app allows the user to explore FSSA with simulated data, data that is provided on the server, or data that the user provides. It allows the user to change parameters as they please, gives visual results of the methods, and also allows the user to compare FSSA results to other spectrum analysis methods such as multivariate singular spectrum analysis. The tool is easy to use and can act as a nice starting point for a user that wishes to perform FSSA as a part of their data analysis.

wplot   *Weighted-Correlations Plot*

Description

This function displays a plot of the weighted-correlation (w-correlation) matrix of functional time series ([fts](fts)) objects that were reconstructed from functional singular spectrum analysis (fssa) objects.

Usage

```
wplot(W, cuts = 20)
```

Arguments

W	A w-correlation matrix.
cuts	An integer that is the number of levels the range of w-correlation values will be divided into.

Note

Refer to fwcor for an example on how to run this function starting from a w-correlation matrix.

[.fts   *Indexing into Functional Time Series*

Description

An indexing method for functional time series ([fts](fts)).

Usage

```
## S3 method for class 'fts'
Y[i = "index"]
```

Arguments

Y	An object of class [fts](fts).
i	The index value.

Value

An object of class `fts`.

See Also

`fts`

Examples

```
## Not run:
require(Rfssa)
load_github_data("https://github.com/haghbinh/Rfssa/blob/master/data/Callcenter.RData")
D <- matrix(sqrt(Callcenter$calls), nrow = 240)
u <- seq(0, 1, length.out = 240) # Define domain of functional data
d <- 22 # number of basis elements
Y <- fts(list(D), list(list(d, "bspline")), list(u))
plot(Y)
plot(Y[10:15])

## End(Not run)
