# Package 'ShinyItemAnalysis'

April 15, 2022

```
Type Package
Title Test and Item Analysis via Shiny
Version 1.4.1
Date 2022-04-14
Description Package including functions and interactive shiny application
     for the psychometric analysis of educational tests, psychological
     assessments, health-related and other types of multi-item
     measurements, or ratings from multiple raters.
License GPL-3

Shin	ItemAnalysis-package	
	ShinvItemAnalysis: Test and Item Analysis via shiny	

#### **Description**

The ShinyItemAnalysis package contains an interactive shiny application for the psychometric analysis of educational tests, psychological assessments, health-related and other types of multi-item measurements, or ratings from multiple raters, which can be accessed using function startShinyItemAnalysis(). The shiny application covers a broad range of psychometric methods and offers data examples, model equations, parameter estimates, interpretation of results, together with a selected R code, and is therefore suitable for teaching psychometric concepts with R. It also allows the users to upload and analyze their own data and to automatically generate analysis reports in PDF or HTML.

Besides, the package provides its own functions for test and item analysis within classical test theory framework (e.g., functions gDiscrim(), ItemAnalysis(), DistractorAnalysis(), or DDplot()), using various regression models (e.g., plotCumulative(), plotAdjacent(), plotMultinomial(), or plotDIFLogistic()), and under IRT framework (e.g., ggWrightMap(), or plotDIFirt()).

Package also contains several demonstration datasets including the HCI dataset from the reference paper by Martinkova and Drabinova (2018).

## **Functions**

- startShinyItemAnalysis()
- DDplot()
- DistractorAnalysis()
- plotDistractorAnalysis()
- gDiscrim()
- ggWrightMap()
- ItemAnalysis()
- plotAdjacent(), plotCumulative(), plotMultinomial()
- plotDIFirt(), plotDIFLogistic()

- plot\_corr()
- recode\_nr()
- ICCrestricted()
- fa\_parallel()

## **Datasets**

- AIBS()
- AttitudesExpulsion()
- BFI2()
- CZmatura()
- CZmaturaS()
- dataMedical()
- dataMedicalgraded()
- dataMedicalkey()
- dataMedicaltest()
- HCI()
- HCIdata()
- HCIgrads()
- HCIkey()
- HCIprepost()
- HCItest()
- HCItestretest()
- HeightInventory()
- LearningToLearn()
- MSclinical()
- NIH()
- TestAnxietyCor()

AIBS

AIBS grant peer review scoring dataset

# Description

The AIBS dataset (Gallo, 2020) comes from the scientific peer review facilitated by the American Institute of Biological Sciences (AIBS) of biomedical applications from and intramural collaborative biomedical research program for 2014–2017. For each proposal, three assigned individual reviewers were asked to provide scores and commentary for the following application criteria: Innovation, Approach/Feasibility, Investigator, and Significance (Impact added as scored criterion in 2014). Each of these criteria is scored on a scale from 1.0 (best) to 5.0 (worst) with a 0.1 gradation, as well as an overall score (1.0–5.0 with a 0.1 gradation). Asynchronous discussion was allowed, although few scores changed post-discussion. The data includes reviewers' self-reported expertise scores (1/2/3, 1 is high expertise) relative to each proposal reviewed, and reviewer / principal investigator demographics. A total of 72 applications ("Standard" or "Pilot") were reviewed in 3 review cycles. The success rate was 34–38 %. Application scores indicate where each application falls among all practically possible applications in comparison with the ideal standard of quality from a perfect application. The dataset was used by Erosheva et al. (2021a) to demonstrate issues of inter-rater reliability in case of restricted samples. For details, see Erosheva et al. (2021b).

## Usage

data(AIBS)

#### **Format**

AIBS is a data. frame consisting of 216 observations on 25 variables. Data describes 72 proposals with 3 ratings each.

ID Proposal ID.

Year Year of the review.

**PropType** Proposal type; "Standard" or "Pilot".

**PIID** Anonymized ID of principal investigator (PI).

6 AIBS

PIOrgType PI's organization type.

PIGender PI's gender membership; "1" females, "2" males.

PIRank PI's rank; "3" full professor, "1" assistant professor.

PIDegree PI's degree; "1" PhD, "2" MD, "3" PhD/MD.

Innovation Innovation score.

Approach Approach score.

Investig Investigator score.

Signif Significance score.

**Impact** Impact score.

Score Scientific merit (overall) score.

ScoreAvg Average of the three overall scores from three different reviewers.

**ScoreAvgAdj** Average of the three overall scores from three different reviewers, increased by multiple of 0.001 of the worst score.

ScoreRank Project rank calculated based on ScoreAvg.

ScoreRankAdj Project rank calculated based on ScoreAvgAdj.

**RevID** Reviewer's ID.

**RevExp** Reviewer's experience.

RevInst Reviewer's institution; "1" academia, "2" government.

RevGender Reviewer's gender; "1" females, "2" males.

**RevRank** Reviewer's rank; "3" full professor, "1" assistant professor.

RevDegree Reviewer's degree; "1" PhD, "2" MD, "3" PhD/MD.

RevCode Reviewer code ("A", "B", "C") in the original wide dataset.

PROMIS Anxiety Scale Dataset

## **Description**

The data contains responses from 766 people sampled from a general population to the PROMIS Anxiety scale (http://www.nihpromis.org) composed of 29 Likert-type questions with a common rating scale (1 = Never, 2 = Rarely, 3 = Sometimes, 4 = Often, and 5 = Always).

## Usage

anxiety

#### **Format**

A data frame with 766 observations on the following 32 variables.

```
age 0 = younger than 65 and <math>1 = 65 and older
```

gender 0 = Male and 1 = Female

education 0 = some college or higher and 1 = high school or lower

- R1 I felt fearful
- R2 I felt frightened
- R3 It scared me when I felt nervous
- R4 I felt anxious
- R5 I felt like I needed help for my anxiety
- R6 I was concerned about my mental health
- R7 I felt upset
- R8 I had a racing or pounding heart
- R9 I was anxious if my normal routine was disturbed
- R10 I had sudden feelings of panic
- R11 I was easily startled
- R12 I had trouble paying attention
- R13 I avoided public places or activities
- R14 I felt fidgety
- R15 I felt something awful would happen
- R16 I felt worried
- R17 I felt terrified
- R18 I worried about other people's reactions to me
- R19 I found it hard to focus on anything other than my anxiety
- R20 My worries overwhelmed me

8 AttitudesExpulsion

- R21 I had twitching or trembling muscles
- R22 I felt nervous
- R23 I felt indecisive
- R24 Many situations made me worry
- R25 I had difficulty sleeping
- R26 I had trouble relaxing
- R27 I felt uneasy
- R28 I felt tense
- R29 I had difficulty calming down

AttitudesExpulsion

Attitudes towards the Expulsion of the Sudeten Germans (dataset)

#### **Description**

Dataset from Kolek et al. (2021) study investigating a video game's effects on implicit and explicit attitudes towards depicted historical events in the short- and long-term. As an intervention tool, a serious game *Czechoslovakia 38–89: Borderlands* was utilized that deals with the expulsion of the Sudeten Germans from the former Czechoslovakia after the WWII. Data consists responses from 145 adults from two groups (experimental and control group) on number of multi-item measurements.

#### **Usage**

AttitudesExpulsion

#### Format

A data.frame with 145 rows and 239 variables:

**ID** anonymous identifier

**Group** C = control or E = experimental group

Gender factor, male or female

**GenderF** *integer*, 1 = female

**Merkel** effect of Merkel speech between the posttest and the delayed posttest, range 0–5, where 0 stands for no effect, 5 for very significant effect

BFI2 9

**Sudety** factor, N = not originally from Czech Borderlands; Y = originally from Czech Borderlands

**Education** factor, V = university; S = high school; Z = elementary school

**Education123** *integer*, same as above, but coded as 3= university; 2= high school; 1= elementary school, meaning higher the number, higher the education

\*PANASpn total PANAS score of positive and negative affect scales

\*PANASp total PANAS score of positive affect scale

\*PANASn total PANAS score of negative affect scale

\*Macro Macro attitude measurement

\*Micro Micro attitude measurement

\*IATeffect Single-Category Implicit association test score

Items beginning with an asterisk have following prefixes in the actual dataset:

pre pretest

post immediate posttest

del one month delayed posttest

Post\_Pre difference between posttest\_pretest

Del\_Post difference between delayed posttest and posttest

#### Source

Kolek, L., Šisler, V., Martinková, P., & Brom, C. (2021). Can video games change attitudes towards history? Results from a laboratory experiment measuring short- and long-term effects. *Journal of Computer Assisted Learning*, *1*–22. doi: 10.1111/jcal.12575

BFI2

BFI2 Dataset

#### **Description**

BFI2 dataset (Hřebíčková et al., 2020) consists of responses of 1,733 respondents (1,003 females, 730 males) to Big Five Inventory 2 (BFI-2). It contains 60 ordinal items, vector of age, education, and vector of gender membership.

#### Usage

data(BFI2)

10 BFI2

#### **Format**

BFI2 is a data. frame consisting of 1,733 observations on 64 variables.

**i1-i60** The BFI items, scored on Likert scale where 1 = Disagree strongly, 2 = Disagree a little, 3 = Neutral; no opinion, 4 = Agree a little, and 5 = Agree strongly. Some items were recoded so that all items are scored in the same direction, see Details.

**Gender** Gender membership, 0 = females, 1 = males.

Age Age in years.

Educ Education, 1 = Basic school, 2 = Secondary technical school, 3 = Secondary general school, 4 = Other secondary school, 5 = Tertiary professional school, 6 = Bachelor degree, 7 = Masters degree, 8 = PhD

#### **Details**

The items prefixed with i are item scores. Items are indicators of 5 latent personality factors/dimensions/domains, which are further broken down into so-called facets. The 5 personality domains are: N = Negative Emotionality, E = Extraversion, O = Open-Mindedness, C = Consciousness and A = Agreeability. These are further broken down into so-called facets, as shown in the following table:

Domain	Facet	Item numbers
E	Sociability (scb)	1, 16, 31, 46
E	Assertiveness (asr)	6, 21, 36, 51
E	Energy Level (enl)	11, 26, 41, 56
A	Compassion (cmp)	2, 17, 32, 47
A	Respectfulness (rsp)	7, 22, 37, 52
A	Trust (trs)	12, 27, 42, 57
C	Organization (org)	3, 18, 33, 48
C	Productiveness (prd)	8, 23, 38, 53
C	Responsibility (rsp)	13, 28, 43, 58
N	Anxiety (anx)	4, 19, 34, 49
N	Depression (dep)	9, 24, 39, 54
N	Emotional Volatility (emt)	14, 29, 44, 59
O	Intellectual Curiosity (int)	10, 25, 40, 55
O	Aesthetic Sensitivity (aes)	5, 20, 35, 50
O	Creative Imagination (crt)	15, 30, 45, 60

In the original instrument, some items are inversely oriented, i.e., the higher score means the lower latent trait. This was the case of items number 3, 4, 5, 8, 9, 11, 12, 16, 17, 22, 23, 24, 25, 26, 28, 29, 30, 31, 36, 37, 42, 44, 45, 47, 48, 49, 50, 51, 55, and 58. These **items have been recoded** for you, i.e., displayed is value of 6 - original score.

In the sample code, alternative item names are provided. These item names can be used to decode the item domain, facet, item number, and whether it was recoded or not. For example, iCorg03r stands for recoded 3rd item (out of 60) from Consciousness domain and Organization facet.

BlisClass-class

BLIS S4 class

## **Description**

Extends mirt's SingleGroupClass directly (meaning all mirt methods that work with that class will work with BlisClass too; make sure mirt is loaded).

#### **Details**

The purpose of the class is to have a custom coef method (see coef,BlisClass-method) dispatched and the original levels with correct response (as a key attribute) stored in the resulting fitted model.

#### **Slots**

orig\_levels *list* of original levels with logical attribute key, which stores the information on which response (level) has been considered as correct. Note that levels not used in the original data are dropped.

#### See Also

```
Other BLIS/BLIRT related: coef,BlisClass-method,fit_blis(),get_orig_levels(),nominal_to_int(),obtain_nrm_def(),print.blis_coefs()
```

12 coef,BlisClass-method

coef,BlisClass-method Get Coefficients from a fitted BLIS model

## **Description**

Extracts item parameters from fitted BLIS model. For BLIRT parametrization, use IRTpars = TRUE in your function call. Contrary to coef, SingleGroupClass-method, response category labels can be displayed in the output using labels = TRUE. On top of that, as BLIS/BLIRT parametrizations utilize the information of correct response category, you can denote these in the output with mark\_correct = TRUE.

#### Usage

```
## S4 method for signature 'BlisClass'
coef(
  object,
    ...,
  CI = 0.95,
  printSE = FALSE,
  IRTpars = FALSE,
  simplify = FALSE,
  labels = FALSE,
  mark_correct = labels
)
```

# Arguments

object	object of class BlisClass, model fitted via fit_blis() or blis().
	Additional arguments. Not utilized at the moment.
CI	numeric, a width of the confidence intervals.
printSE	logical, print standard errors instead of CI? Defaults to FALSE.
IRTpars	$logical,  {\rm convert}   {\rm slope}   {\rm intercept}   {\rm parameters}   {\rm inte}   {\rm IRT}  {\rm parameters}   ({\rm i.e.}    {\rm BLIRT})?$ Defaults to FALSE.
simplify	$logical$ , return coefficients as a matrix, instead of list? Defaults to FALSE. $Not\ implemented\ yet.$
labels	logical, if TRUE, show response labels (e.g. "A", "B", "C") instead of response numeric indices (e.g. 0, 1, 2). Defaults to FALSE.
mark_correct	<i>logical</i> , mark the correct response with an asterisk symbol. Applicable only if labels is TRUE (in which case, mark_correct defaults to TRUE).

## Value

List of item coefficients of S3 class blis\_coefs, so the resulting output of coef() call is formatted to display only first 3 digits (you can opt for different rounding via the print.blis\_coefs method, see the examples). Note that the list-object returned invisibly has the raw coefficients stored in it.

Other BLIS/BLIRT related: BlisClass-class, fit_blis(), get_orig_levels(), nominal_to_int(), obtain_nrm_def(), print.blis_coefs()
```

## **Examples**

```
fitted_blis <- fit_blis(HCItest[, 1:20], HCIkey)

# BLIS coefs
coef(fitted_blis)

# BLIRT coefs
coef(fitted_blis, IRTpars = TRUE)

# store raw coefs
blis_coefs <- coef(fitted_blis)

# print coefs rounded to 2 digits
print(blis_coefs, digits = 2)</pre>
```

CZmatura

CZmatura dataset

## **Description**

The CZmatura dataset comes from matura exam in mathematics. The exam was assigned in 2019 to students from Grade 13, at the end of their secondary education. Original data available from https://cermat.cz/.

#### Usage

```
data(CZmatura)
```

#### **Format**

CZmatura is a data. frame consisting of 15,702 observations on 75 variables.

```
SchType School type code.
```

```
FirstAtt First attempt; "1" yes, "0" no.
```

SchTypeGY School type gymnasium; "1" yes, "0" no.

o1 - o26.2 Item answers.

**b1 – b26** Scored item answers.

**Total** Total score, calculated as sum of item scores (0 - 50).

IRTscore Score estimated from GPCM/2PL model.

IRTscoreSE SE of score estimated from GPCM/2PL model.

14 CZmaturaS

Dichotomous dataset of admission test to medical school

#### **Description**

The dataMedical dataset consists of the responses of 2,392 subjects (750 males, 1,633 females and 9 subjects without gender specification) to admission test to a medical school. It contains 100 items. A correct answer is coded as "1" and incorrect answer as "0". Missing answers were evaluated as incorrect, i.e. "0".

## Usage

dataMedical

#### **Format**

A dataMedical is a data.frame consisting of 2,392 observations on the following 102 variables.

**X** The first 100 columns represent dichotomously scored items of the test.

**gender** Variable describing gender; values "0" and "1" refer to males and females.

**StudySuccess** Criterion variable; value "1" means that student studies standardly, "0" otherwise (e.g., leaving or interrupting studies).

Dataset of admission test to medical school

# Description

The dataMedicaltest dataset consists of the responses of 2,392 subjects (750 males, 1,633 females and 9 subjects without gender specification) to multiple-choice admission test to a medical school. It contains 100 items, possible answers were A, B, C, D, while any combination of these can be correct.

## Usage

data(dataMedicaltest)

#### **Format**

A dataMedicaltest is a data. frame consisting of 2,392 observations on the following 102 variables.

**X** The first 100 columns represent items answers.

gender Variable describing gender; values "0" and "1" refer to males and females.

**StudySuccess** Criterion variable; value "1" means that student studies standardly, "0" otherwise (e.g., leaving or interrupting studies).

DDplot

Plot difficulties and discriminations/item validity

## **Description**

Plots difficulty and (generalized) discrimination or criterion validity for items of the multi-item measurement test using the **ggplot2** package. Difficulty and discrimination/validity indices are plotted for each item, items are ordered by their difficulty.

# Usage

```
DDplot(
  Data,
  item.names,
  discrim = "ULI",
  k = 3,
  l = 1,
  u = 3,
  maxscore,
  minscore,
  bin = FALSE,
  cutscore,
```

DDplot 19

```
average.score = FALSE,
 thr = 0.2,
 criterion = "none",
 val_type = "simple",
 data
)
```

# Arguments

Data	numeric: binary or ordinal data matrix or data.frame which rows represent examinee answers (1 correct, 0 incorrect, or ordinal item scores) and columns correspond to the items.
item.names	character: the names of items. If not specified, the names of $\mbox{\it Data}$ columns are used.
discrim	character: type of discrimination index to be calculated. Possible values are "ULI" (default), "RIT", "RIR", and "none". See <b>Details</b> .
k	numeric: number of groups to which data may be divided by the total score to estimate discrimination using discrim = "ULI". Default value is 3. See <b>Details</b> .
1	numeric: lower group. Default value is 1. See <b>Details</b> .
u	numeric: upper group. Default value is 3. See <b>Details</b> .
maxscore	numeric: maximal scores of items. If single number is provided, the same maximal score is used for all items. If missing, vector of achieved maximal scores is calculated and used in calculations.
minscore	numeric: minimal scores of items. If single number is provided, the same maximal score is used for all items. If missing, vector of achieved maximal scores is calculated and used in calculations.
bin	logical: should the ordinal data be binarized? Default value is FALSE. In case that bin = TRUE, all values of Data equal or greater than cutscore are marked as 1 and all values lower than cutscore are marked as 0.
cutscore	numeric: cut-score used to binarize Data. If numeric, the same cut-score is used for all items. If missing, vector of maximal scores is used in calculations.
average.score	logical: should average score of the item be displayed instead of difficulty? Default value is FALSE. See <b>Details</b> .
thr	numeric: value of discrimination threshold. Default value is 0.2. With thr = NULL, no horizontal line is displayed in the plot.
criterion	numeric or logical vector: values of criterion. If supplied, disrim argument is ignored and item-criterion correlation (validity) is displayed instead. Default value is "none".
val_type	character: criterion validity measure. Possible values are "simple" (correlation between item score and validity criterion; default) and "index" (item validity index calculated as cor(item, criterion) * sqrt(((N -1) / N) * var(item)), where N is number of respondents, see Allen & Yen, 1979, Ch. 6.4, for details). The argument is ignored if user does not supply any criterion.
data	deprecated. Use argument Data instead.

#### **Details**

20

Discrimination is calculated using method specified in discrim. Default option "ULI" calculates difference in ratio of correct answers in upper and lower third of students. "RIT" index calculates correlation between item score and test total score. "RIR" index calculates correlation between item score and total score for the rest of the items. With option "none", only difficulty is displayed.

"ULI" index can be generalized using arguments k, 1 and u. Generalized ULI discrimination is then computed as follows: The function takes data on individuals, computes their total test score and then divides individuals into k groups. The lower and upper group are determined by 1 and u parameters, i.e. 1-th and u-th group where the ordering is defined by increasing total score.

For ordinal data, difficulty is defined as a relative score:

```
(achieved - minimal)/(maximal - minimal)
```

Minimal score can be specified by minscore, maximal score can be specified by maxscore. Average score of items can be displayed with argument average.score = TRUE. Note that for binary data difficulty estimate is the same as average score of the item.

Note that all correlations are estimated using Pearson correlation coefficient.

22 DistractorAnalysis

## **Description**

Performs distractor analysis for each item and optional number of groups.

## Usage

```
DistractorAnalysis(
  Data,
  key,
  item = "all",
  p.table = FALSE,
  num.groups = 3,
  criterion = NULL,
  crit.discrete = FALSE,
  cut.points,
  data,
  matching,
  match.discrete
)
```

## **Arguments**

Data	character: data matrix or data.frame with rows representing unscored item responses from a multiple-choice test and columns corresponding to the items.
key	character: answer key for the items. The key must be a vector of the same length as ncol(Data). In case it is not provided, criterion needs to be specified.
item	numeric or character: either character "all" to apply for all items (default), or a vector of item names (column names of Data), or item identifiers (integers specifying the column number).
p.table	logical: should the function return the proportions? If $\mbox{\sf FALSE}$ (default), the counts are returned.
num.groups	numeric: number of groups to which are the respondents split.
criterion	numeric: numeric vector. If not provided, total score is calculated and distractor analysis is performed based on it.
crit.discrete	logical: is criterion discrete? Default value is FALSE. See details.
cut.points	numeric: numeric vector specifying cut points of criterion. See details.
data	deprecated. Use argument Data instead.
matching	deprecated. Use argument criterion instead.
match.discrete	deprecated. Use argument crit.discrete instead.

# **Details**

This function is an adapted version of the distractor.analysis() function from CTT package. In case that no criterion is provided, the scores are calculated using the item Data and key. The respondents are by default split into the num.groups-quantiles and the number (or proportion) of respondents in each quantile is reported with respect to their answers. In case that criterion is discrete (crit.discrete = TRUE), criterion is split based on its unique levels. Other cut points can be specified via cut.points argument.

# distractor analysis using discrete criterion
DistractorAnalysis(Data, key, criterion = criterion, crit.discrete = TRUE)
# distractor analysis using groups specified by cut.points
DistractorAnalysis(Data, key, cut.points = seq(10, 96, 10))
## End(Not run)
```

24 fa\_parallel

## **Description**

Computes the eigenvalues of the sample correlation matrix and the eigenvalues obtained from a random correlation matrix for which no factors/components are assumed. By default, the function utilizes a modified Horn's (1965) method, which – instead of mean – uses 95th percentile of each item eigenvalues sampling distribution as a threshold to find the optimal number of factors/components.

## Usage

```
fa_parallel(
  Data,
  cor = "pearson",
  n_obs = NULL,
  method = "pca",
  threshold = "quantile",
  p = 0.95,
  n_iter = 20,
  plot = TRUE,
  show_kaiser = TRUE,
  fm = "minres",
  use = "pairwise",
  ...
)
```

# Arguments

Data	data.frame or matrix, dataset (where rows are observations and columns items) or correlation matrix (recognized automatically).
cor	<i>character</i> , how to calculate the correlation matrix of the real data. Can be either pearson (default), tetrachoric or polychoric. Unambiguous abbreviations accepted.
n_obs	<i>integer</i> , in case you provided the correlation matrix directly as the input, you have to provide the number of observations in the original dataset.
method	<i>character</i> , either fa, pca, or both (the default). Which method to use for the eigenvalues simulation and computation.
threshold	<i>character</i> , whether to use traditionall Horn's method or more recent and well-performing quantile one. Either mean or quantile (default). Can be abbreviated.
p	numeric (0–1), probability for which the sample quantile is produced. Defaults to .95. Ignored if threshold = "mean".
n_iter	<i>integer</i> , number of iterations, i.e. the number of zero-factor multivariate normal distributions to sample. Defaults to 20.
plot	<i>logical</i> , if TRUE (the default), show the plot along with the function results. To create the plot from the resulting object afterwards, call plot().
show_kaiser	logical, whether to show Kaiser boundary in the plot (the default) or not.
fm	character, factoring method. See psych::fa() from the package psych::psych().

fa\_parallel 25

use

an optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete", or "pairwise.complete.obs".

... Arguments passed on to psych::polychoric

correct Correction value to use to correct for continuity in the case of zero entry cell for tetrachoric, polychoric, polybi, and mixed.cor. See the examples for the effect of correcting versus not correcting for continuity.

smooth if TRUE and if the tetrachoric/polychoric matrix is not positive definite, then apply a simple smoothing algorithm using cor.smooth

global When finding pairwise correlations, should we use the global values of the tau parameter (which is somewhat faster), or the local values (global=FALSE)? The local option is equivalent to the polycor solution, or to doing one correlation at a time. global=TRUE borrows information for one item pair from the other pairs using those item's frequencies. This will make a difference in the presence of lots of missing data. With very small sample sizes with global=FALSE and correct=TRUE, the function will fail (for as yet underdetermined reasons.

weight A vector of length of the number of observations that specifies the weights to apply to each case. The NULL case is equivalent of weights of 1 for all cases.

progress Show the progress bar (if not doing multicores)

ML ML=FALSE do a quick two step procedure, ML=TRUE, do longer maximum likelihood — very slow! Deprecated

delete Cases with no variance are deleted with a warning before proceeding. max.cat The maximum number of categories to bother with for polychoric.

#### **Details**

Horn proposed a solution to the problem of optimal factor number identification using an approach based on a Monte Carlo simulation.

First, several (20 by default) zero-factor p-variate normal distributions (where p is the number of columns) are obtained, and  $p \times p$  correlation matrices are computed for them. Eigenvalues of each matrix is then calculated in order to get an eigenvalues sampling distribution for each simulated variable.

Traditionally, Horn obtains an average of each sampling distribution and these averages are used as a threshold which is compared with eigenvalues of the original, real data. However, *usage of the mean was later disputed* by Buja & Eyuboglu (1992), and 95th percentile of eigenvalues sampling distribution was suggested as a more accurate threshold. This, more recent method is used by default in the function.

## Value

An object of class data. frame and sia\_parallel. Can be plotted using plot().

fa_parallel(items)
fa_parallel(items, threshold = "mean") # traditional Horn's method

## End(Not run)</pre>
```

fit\_blis

Fit Baseline-category Logit Intercept-Slope (BLIS) model on nominal data

#### **Description**

blis fits the IRT Nominal Response Model to data from multiple-choice tests, while accounting for the correct answer and treating this option as a baseline in this baseline-category logit model. The intercept-slope parametrization in BLIS can be converted to IRT (difficulty-discrimination) parametrization (BLIRT).

## **Usage**

```
fit_blis(Data, key, ...)
blis(Data, key, ...)
```

#### **Arguments**

Data

*data.frame* or *tibble* with all columns being factors. Support for *matrix* is limited and behavior not guaranteed.

key

A single-column data.frame, (**not** matrix) tibble or - preferably - a factor vector of levels considered as correct responses.

. . .

Arguments passed on to mirt::mirt

SE logical; estimate the standard errors by computing the parameter information matrix? See SE. type for the type of estimates available

covdata a data.frame of data used for latent regression models

formula an R formula (or list of formulas) indicating how the latent traits can be regressed using external covariates in covdata. If a named list of formulas is supplied (where the names correspond to the latent trait names in model) then specific regression effects can be estimated for each factor. Supplying a single formula will estimate the regression parameters for all latent traits by default

SE. type type of estimation method to use for calculating the parameter information matrix for computing standard errors and wald tests. Can be:

- 'Richardson', 'forward', or 'central' for the numerical Richardson, forward difference, and central difference evaluation of observed Hessian matrix
- 'crossprod' and 'Louis' for standard error computations based on the variance of the Fisher scores as well as Louis' (1982) exact computation of the observed information matrix. Note that Louis' estimates can take a long time to obtain for large sample sizes and long tests
- 'sandwich' for the sandwich covariance estimate based on the 'crossprod' and 'Oakes' estimates (see Chalmers, 2018, for details)
- 'sandwich.Louis' for the sandwich covariance estimate based on the 'crossprod' and 'Louis' estimates
- 'Oakes' for Oakes' (1999) method using a central difference approximation (see Chalmers, 2018, for details)
- 'SEM' for the supplemented EM (disables the accelerate option automatically; EM only)
- 'Fisher' for the expected information, 'complete' for information based on the complete-data Hessian used in EM algorithm
- 'MHRM' and 'FMHRM' for stochastic approximations of observed information matrix based on the Robbins-Monro filter or a fixed number of MHRM draws without the RM filter. These are the only options supported when method = 'MHRM'
- 'numerical' to obtain the numerical estimate from a call to optim when method = 'BL'

Note that both the 'SEM' method becomes very sensitive if the ML solution has has not been reached with sufficient precision, and may be further sensitive if the history of the EM cycles is not stable/sufficient for convergence of the respective estimates. Increasing the number of iterations (increasing NCYCLES and decreasing TOL, see below) will help to improve the accuracy,

and can be run in parallel if a mirtCluster object has been defined (this will be used for Oakes' method as well). Additionally, inspecting the symmetry of the ACOV matrix for convergence issues by passing technical = list(symmetric = FALSE) can be helpful to determine if a sufficient solution has been reached

method a character object specifying the estimation algorithm to be used. The default is 'EM', for the standard EM algorithm with fixed quadrature, 'QMCEM' for quasi-Monte Carlo EM estimation, or 'MCEM' for Monte Carlo EM estimation. The option 'MHRM' may also be passed to use the MH-RM algorithm, 'SEM' for the Stochastic EM algorithm (first two stages of the MH-RM stage using an optimizer other than a single Newton-Raphson iteration), and 'BL' for the Bock and Lieberman approach (generally not recommended for longer tests).

The 'EM' is generally effective with 1-3 factors, but methods such as the 'QMCEM', 'MCEM', 'SEM', or 'MHRM' should be used when the dimensions are 3 or more. Note that when the optimizer is stochastic the associated SE.type is automatically changed to SE.type = 'MHRM' by default to avoid the use of quadrature

optimizer a character indicating which numerical optimizer to use. By default, the EM algorithm will use the 'BFGS' when there are no upper and lower bounds box-constraints and 'nlminb' when there are.

Other options include the Newton-Raphson ('NR'), which can be more efficient than the 'BFGS' but not as stable for more complex IRT models (such as the nominal or nested logit models) and the related 'NR1' which is also the Newton-Raphson but consists of only 1 update that has been coupled with RM Hessian (only applicable when the MH-RM algorithm is used). The MH-RM algorithm uses the 'NR1' by default, though currently the 'BFGS', 'L-BFGS-B', and 'NR' are also supported with this method (with fewer iterations by default) to emulate stochastic EM updates. As well, the 'Nelder-Mead' and 'SANN' estimators are available, but their routine use generally is not required or recommended.

Additionally, estimation subroutines from the Rsolnp and nloptr packages are available by passing the arguments 'solnp' and 'nloptr', respectively. This should be used in conjunction with the solnp\_args and nloptr\_args specified below. If equality constraints were specified in the model definition only the parameter with the lowest parnum in the pars = 'values' data.frame is used in the estimation vector passed to the objective function, and group hyper-parameters are omitted. Equality an inequality functions should be of the form function(p,optim\_args), where optim\_args is a list of internally parameters that largely can be ignored when defining constraints (though use of browser() here may be helpful)

dentype type of density form to use for the latent trait parameters. Current options include

- 'Gaussian' (default) assumes a multivariate Gaussian distribution with an associated mean vector and variance-covariance matrix
- 'empiricalhist' or 'EH' estimates latent distribution using an empirical histogram described by Bock and Aitkin (1981). Only applicable for unidimensional models estimated with the EM algorithm. For

- this option, the number of cycles, TOL, and quadpts are adjusted accommodate for less precision during estimation (namely: TOL = 3e-5, NCYCLES = 2000, quadpts = 121)
- 'empiricalhist\_Woods' or 'EHW' estimates latent distribution using an empirical histogram described by Bock and Aitkin (1981), with the same specifications as in dentype = 'empiricalhist', but with the extrapolation-interpolation method described by Woods (2007). NOTE: to improve stability in the presence of extreme response styles (i.e., all highest or lowest in each item) the technical option zeroExtreme = TRUE may be required to down-weight the contribution of these problematic patterns
- 'Davidian-#' estimates semi-parametric Davidian curves described by Woods and Lin (2009), where the # placeholder represents the number of Davidian parameters to estimate (e.g., 'Davidian-6' will estimate 6 smoothing parameters). By default, the number of quadpts is increased to 121, and this method is only applicable for unidimensional models estimated with the EM algorithm
- constrain a list of user declared equality constraints. To see how to define the parameters correctly use pars = 'values' initially to see how the parameters are labeled. To constrain parameters to be equal create a list with separate concatenated vectors signifying which parameters to constrain. For example, to set parameters 1 and 5 equal, and also set parameters 2, 6, and 10 equal use constrain = list(c(1,5),c(2,6,10)). Constraints can also be specified using the mirt.model syntax (recommended)
- parprior a list of user declared prior item probabilities. To see how to define the parameters correctly use pars = 'values' initially to see how the parameters are labeled. Can define either normal (e.g., intercepts, lower/guessing and upper bounds), log-normal (e.g., for univariate slopes), or beta prior probabilities. To specify a prior the form is c('priortype', ...), where normal priors are parprior = list(c(parnumbers, 'norm', mean, sd)), parprior = list(c(parnumbers, 'lnorm', log\_mean, log\_sd)) for log-normal, and parprior = list(c(parnumbers, 'beta', alpha, beta)) for beta, and parprior = list(c(parnumbers, 'expbeta', alpha, beta)) for the beta distribution after applying the function plogis to the input value (note, this is specifically for applying a beta prior to the lower/upper-bound parameters in 3/4PL models). Priors can also be specified using mirt.model syntax (recommended)
- calcNull logical; calculate the Null model for additional fit statistics (e.g., TLI)? Only applicable if the data contains no NA's and the data is not overly sparse
- draws the number of Monte Carlo draws to estimate the log-likelihood for the MH-RM algorithm. Default is 5000
- survey.weights a optional numeric vector of survey weights to apply for each case in the data (EM estimation only). If not specified, all cases are weighted equally (the standard IRT approach). The sum of the survey.weights must equal the total sample size for proper weighting to be applied
- quadpts number of quadrature points per dimension (must be larger than 2). By default the number of quadrature uses the following scheme: switch(as.character(nfact), '1'=6

However, if the method input is set to 'QMCEM' and this argument is left blank then the default number of quasi-Monte Carlo integration nodes will be set to 5000 in total

TOL convergence threshold for EM or MH-RM; defaults are .0001 and .001. If SE.type = 'SEM' and this value is not specified, the default is set to 1e-5. To evaluate the model using only the starting values pass TOL = NaN, and to evaluate the starting values without the log-likelihood pass TOL = NA

gpcm\_mats a list of matrices specifying how the scoring coefficients in the (generalized) partial credit model should be constructed. If omitted, the standard gpcm format will be used (i.e., seq(0,k,by=1) for each trait). This input should be used if traits should be scored different for each category (e.g., matrix(c(0:3,1,0,0,0),4,2) for a two-dimensional model where the first trait is scored like a gpcm, but the second trait is only positively indicated when the first category is selected). Can be used when itemtypes are 'gpcm' or 'Rasch', but only when the respective element in gpcm\_mats is not NULL

grsm.block an optional numeric vector indicating where the blocking should occur when using the grsm, NA represents items that do not belong to the grsm block (other items that may be estimated in the test data). For example, to specify two blocks of 3 with a 2PL item for the last item: grsm.block = c(rep(1,3),rep(2,3),NA). If NULL the all items are assumed to be within the same group and therefore have the same number of item categories

rsm.block same as grsm.block, but for 'rsm' blocks

monopoly.k a vector of values (or a single value to repeated for each item) which indicate the degree of the monotone polynomial fitted, where the monotone polynomial corresponds to monopoly.k \* 2 + 1 (e.g., monopoly.k = 2 fits a 5th degree polynomial). Default is monopoly.k = 1, which fits a 3rd degree polynomial

large a logical indicating whether unique response patterns should be obtained prior to performing the estimation so as to avoid repeating computations on identical patterns. The default TRUE provides the correct degrees of freedom for the model since all unique patterns are tallied (typically only affects goodness of fit statistics such as G2, but also will influence nested model comparison methods such as anova(mod1, mod2)), while FALSE will use the number of rows in data as a placeholder for the total degrees of freedom. As such, model objects should only be compared if all flags were set to TRUE or all were set to FALSE

Alternatively, if the collapse table of frequencies is desired for the purpose of saving computations (i.e., only computing the collapsed frequencies for the data onte-time) then a character vector can be passed with the arguement large = 'return' to return a list of all the desired table information used by mirt. This list object can then be reused by passing it back into the large argument to avoid re-tallying the data again (again, useful when the dataset are very large and computing the tabulated data is computationally burdensome). This strategy is shown below:

- Pass the organized data to all estimation functions e.g., mod <-mirt(Science,1,large = internaldat)
- GenRandomPars logical; generate random starting values prior to optimization instead of using the fixed internal starting values?
- accelerate a character vector indicating the type of acceleration to use. Default is 'Ramsay', but may also be 'squarem' for the SQUAREM procedure (specifically, the gSqS3 approach) described in Varadhan and Roldand (2008). To disable the acceleration, pass 'none'
- verbose logical; print observed- (EM) or complete-data (MHRM) log-likelihood after each iteration cycle? Default is TRUE
- solnp\_args a list of arguments to be passed to the solnp::solnp() function for equality constraints, inequality constraints, etc
- nloptr\_args a list of arguments to be passed to the nloptr::nloptr() function for equality constraints, inequality constraints, etc
- spline\_args a named list of lists containing information to be passed to the bs (default) and ns for each spline itemtype. Each element must refer to the name of the itemtype with the spline, while the internal list names refer to the arguments which are passed. For example, if item 2 were called 'read2', and item 5 were called 'read5', both of which were of itemtype 'spline' but item 5 should use the ns form, then a modified list for each input might be of the form:
  - spline\_args = list(read2 = list(degree = 4), read5 = list(fun = 'ns', knots = c(-2,2))
  - This code input changes the bs() splines function to have a degree = 4 input, while the second element changes to the ns() function with knots set a c(-2,2)
- control a list passed to the respective optimizers (i.e., optim(), nlminb(), etc). Additional arguments have been included for the 'NR' optimizer: 'tol' for the convergence tolerance in the M-step (default is TOL/1000), while the default number of iterations for the Newton-Raphson optimizer is 50 (modified with the 'maxit' control input)
- technical a list containing lower level technical parameters for estimation. May be:
  - **NCYCLES** maximum number of EM or MH-RM cycles; defaults are 500 and 2000
  - **MAXQUAD** maximum number of quadratures, which you can increase if you have more than 4GB or RAM on your PC; default 20000
  - **theta\_lim** range of integration grid for each dimension; default is c(-6,6) **set.seed** seed number used during estimation. Default is 12345
  - **SEtol** standard error tolerance criteria for the S-EM and MHRM computation of the information matrix. Default is 1e-3
  - **symmetric** logical; force S-EM/Oakes information matrix estimates to be symmetric? Default is TRUE so that computation of standard errors are more stable. Setting this to FALSE can help to detect solutions that have not reached the ML estimate
  - **SEM\_window** ratio of values used to define the S-EM window based on the observed likelihood differences across EM iterations. The default

- is c(0,1 -SEtol), which provides nearly the very full S-EM window (i.e., nearly all EM cycles used). To use the a smaller SEM window change the window to to something like c(.9,.999) to start at a point farther into the EM history
- warn logical; include warning messages during estimation? Default is TRUE
- **message** logical; include general messages during estimation? Default is TRUE
- customK a numeric vector used to explicitly declare the number of response categories for each item. This should only be used when constructing mirt model for reasons other than parameter estimation (such as to obtain factor scores), and requires that the input data all have 0 as the lowest category. The format is the same as the extract.mirt(mod,'K') slot in all converged models
- customPriorFun a custom function used to determine the normalized density for integration in the EM algorithm. Must be of the form function(Theta, Etable){...}, and return a numeric vector with the same length as number of rows in Theta. The Etable input contains the aggregated table generated from the current E-step computations. For proper integration, the returned vector should sum to 1 (i.e., normalized). Note that if using the Etable it will be NULL on the first call, therefore the prior will have to deal with this issue accordingly
- **zeroExtreme** logical; assign extreme response patterns a survey.weight of 0 (formally equivalent to removing these data vectors during estimation)? When dentype = 'EHW', where Woods' extrapolation is utilized, this option may be required if the extrapolation causes expected densities to tend towards positive or negative infinity. The default is FALSE
- customTheta a custom Theta grid, in matrix form, used for integration. If not defined, the grid is determined internally based on the number of quadpts
- **delta** the deviation term used in numerical estimates when computing the ACOV matrix with the 'forward' or 'central' numerical approaches, as well as Oakes' method with the Richardson extrapolation. Default is 1e-5
- parallel logical; use the parallel cluster defined by mirtCluster? Default
  is TRUE
- **internal\_constraints** logical; include the internal constraints when using certain IRT models (e.g., 'grsm' itemtype). Disable this if you want to use special optimizers such as the solnp. Default is TRUE
- gain a vector of two values specifying the numerator and exponent values for the RM gain function  $(val1/cycle)^val2$ . Default is c(0.10,0.75)
- **BURNIN** number of burn in cycles (stage 1) in MH-RM; default is 150
- SEMCYCLES number of SEM cycles (stage 2) in MH-RM; default is 100
- **MHDRAWS** number of Metropolis-Hasting draws to use in the MH-RM at each iteration; default is 5
- **MHcand** a vector of values used to tune the MH sampler. Larger values will cause the acceptance ratio to decrease. One value is required

for each group in unconditional item factor analysis (mixedmirt() requires additional values for random effect). If null, these values are determined internally, attempting to tune the acceptance of the draws to be between .1 and .4

MHRM\_SE\_draws number of fixed draws to use when SE=TRUE and SE. type = 'FMHRM' and the maximum number of draws when SE. type = 'MHRM'.

Default is 2000

MCEM\_draws a function used to determine the number of quadrature points to draw for the 'MCEM' method. Must include one argument which indicates the iteration number of the EM cycle. Default is function(cycles) 500 + (cycles -1)\*2, which starts the number of draws at 500 and increases by 2 after each full EM iteration

info\_if\_converged logical; compute the information matrix when using the MH-RM algorithm only if the model converged within a suitable number of iterations? Default is TRUE

logLik\_if\_converged logical; compute the observed log-likelihood when using the MH-RM algorithm only if the model converged within a suitable number of iterations? Default is TRUE

keep\_vcov\_PD logical; attempt to keep the variance-covariance matrix of the latent traits positive definite during estimation in the EM algorithm?
 This generally improves the convergence properties when the traits are highly correlated. Default is TRUE

#### **Details**

For the details on coef method dispatched for fitted BLIS model, see coef,BlisClass-method. To get more on the class, see BlisClass.

#### Value

Fitted model of class BlisClass (extending standard mirt's SingleGroupClass).

```
Other BLIS/BLIRT related: BlisClass-class, coef,BlisClass-method, get_orig_levels(), nominal_to_int(), obtain_nrm_def(), print.blis_coefs()
```

34 gDiscrim

## **Examples**

```
fitted_blis <- fit_blis(HCItest[, 1:20], HCIkey, SE = TRUE)
coef(fitted_blis)
coef(fitted_blis)$`Item 12`
coef(fitted_blis, IRTpars = TRUE)
coef(fitted_blis, IRTpars = TRUE, CI = 0.90) # 90% CI instead of 95% CI
coef(fitted_blis, IRTpars = TRUE, printSE = TRUE) # SE instead of CI</pre>
```

gDiscrim

Compute generalized item discrimination

## Description

Generalized version of discrimination index ULI. The function enumerates the ability of an item to distinguish between individuals from upper (U) vs. lower (L) ability groups, i.e. between respondents with high vs. low overall score on the test. Number of groups, as well as upper and lower groups can be specified by user. You can also manually supply the maximal and minimal scores when the theoretical range of item score is known. Note that if the *observed* item range is zero NaN is returned.

## Usage

```
gDiscrim(Data, k = 3, l = 1, u = 3, maxscore, minscore, x, ...)
```

#### **Arguments**

Data	matrix or data.frame of items to be examined. Rows represent respondents, columns represent items.
k	numeric: number of groups to which may be Data divided by the total score. Default value is 3. See <b>Details</b> .
1	numeric: lower group. Default value is 1. See Details.
u	numeric: upper group. Default value is 3. See <b>Details</b> .
maxscore	numeric: maximal score in ordinal items. If missing, vector of obtained maximal scores is imputed. See <b>Details</b> .
minscore	numeric: minimal score in ordinal items. If missing, vector of obtained minimal scores is imputed. See <b>Details</b> .
x	deprecated. Use argument Data instead.
	Arguments passed on to base::findInterval
	rightmost.closed logical; if true, the rightmost interval, vec[N-1] vec[N] is treated as <i>closed</i> , see below.
	all.inside logical; if true, the returned indices are coerced into 1,, N-1, i.e., 0 is mapped to 1 and N to N-1.
	left.open logical; if true all the intervals are open at left and closed at right; in the formulas below, $\leq$ should be swapped with $<$ (and $>$ with $\geq$ ), and rightmost.closed means 'leftmost is closed'. This may be useful, e.g., in survival analysis computations.

gDiscrim 35

#### **Details**

The function computes total test scores for all respondents and then divides the respondents into k groups. The lower and upper groups are determined by 1 and u parameters, i.e., l-th and u-th group where the ordering is defined by increasing total score.

In ordinal items, difficulty is calculated as difference of average score divided by range (maximal possible score maxscore minus minimal possible score minscore for given item).

Discrimination is calculated as difference in difficulty between upper and lower group.

#### Note

gDiscrim is used by DDplot() function.

get\_orig\_levels

Get Original Levels from a Fitted BLIS model

## Description

Just a simple accessor to original levels and correct key stored in fitted BLIS model.

#### Usage

```
get_orig_levels(object)
```

## **Arguments**

object

object of class BlisClass, model fitted via fit\_blis() or blis().

## Value

list of the original levels and correct key. Key is stored as an attribute key for every individual item.

#### See Also

```

ggWrightMap 37

ggWrightMap	Plot person-item map (Wright map) using ggplot2		
-------------	---	--	--

#### **Description**

This function allows to generate Wright map (also called person-item map) using ggplot() function from the **ggplot2** package. Wright map is used to jointly display histogram of abilities (or other measured trait) and item difficulty parameters. Function takes pre-estimated parameter estimates, such as those obtained from an IRT model.

## Usage

```
ggWrightMap(
  theta,
  b,
  binwidth = 0.5,
  color = "blue",
  size = 15,
  item.names,
  ylab.theta = "Respondent latent trait",
  ylab.b = "Item difficulty",
  rel_widths = c(1, 1)
)
```

## **Arguments**

```
theta
                   numeric: vector of ability estimates.
                   numeric: vector of difficulty estimates.
binwidth
                   numeric: the width of the bins of histogram.
color
                   character: color of histogram.
                   text size in pts.
size
                   names of items to be displayed.
item.names
ylab.theta
                   character: description of y-axis for the histogram.
                   character: description of y-axis for the plot of difficulty estimates.
ylab.b
                   numeric: vector of length 2 specifying ratio of "facet's" widths.
rel_widths
```

HCI

Homeostasis Concept Inventory dichotomous dataset

#### **Description**

HCI dataset consists of the dichotomously scored responses of 651 students (405 males, 246 females) to Homeostasis Concept Inventory (HCI) multiple-choice test. It contains 20 items, vector of gender membership and identificator whether students plan to major in life sciences.

# Usage

HCI

HCIdata 39

#### **Format**

HCI is a data. frame consisting of 651 observations on the 22 variables.

Item1-Item20 Dichotomously scored items of the HCI test.

gender Gender membership, "0" males, "1" females.

major Identificator whether student plans to major in the life sciences.

total Total score

**HCIdata** 

Homeostasis concept inventory full dataset

## Description

HCIdata dataset consists of the responses of 669 students (405 males, 246 females, 18 without gender specification) to Homeostasis Concept Inventory (HCI) multiple-choice test. It contains answers to 20 multiple-choice items, scored items, total score, gender membership, identifier whether students plan to major in science, study year, minority membership, identifier whether English is the student's first language, and type of school.

#### Usage

data(HCIdata)

40 HCIdata

#### **Format**

HCIdata is a data. frame consisting of 669 observations on the 47 variables.

A1-A20 Multiple-choice items of the HCI test.

QR1-QR20 Scored items of the HCI test, "0" incorrect, "1" correct.

total Total test score.

gender Gender membership, "M" males, "F" females, "none" undisclosed.

major Identifier whether students plans to major in the life sciences.

yearc5 Study year.

minority Minority membership, "maj" majority, "min" Black/Hispanic minority, "none" undisclosed.

**EnglishF** Identifier whether English is the student's first language.

**typeS** Course type, "allied" allied health, "majors" physiology courses for science majors, "mixed majors" courses for non-majors.

**typeSCH** Type of school, "AC" associate's college, "BCAS" baccalaureate college: arts and sciences focus, "R1" research university, "MCU" master's college and university.

HCIgrads 41

**HCIgrads** 

Homeostasis concept inventory dataset of graduate students

## **Description**

HCIgrads dataset consists of the responses of 10 graduate students to Homeostasis Concept Inventory (HCI) multiple-choice test. It contains answers to 20 multiple-choice items, scored items, and total test score.

#### Usage

```
data(HCIgrads)
```

#### **Format**

HCIgrads is a data. frame consisting of 10 observations on the 42 variables.

A1-A20 Multiple-choice items of the HCI test.

QR1-QR20 Scored items of the HCI test, "0" incorrect, "1" correct.

total Total test score.

HeightInventory

Height inventory dataset

#### **Description**

HeightInventory dataset consists of the responses of 4,885 respondents (1479 males, 3406 females) to a Height Inventory (Rečka, 2018). It contains 26 ordinal items of self-perceived height rated on a scale "1" strongly disagree, "2" disagree, "3" agree, "4" strongly agree, vector of self-reported heights (in centimeters), and vector of gender membership.

```
data(HeightInventory)
```

46 HeightInventory

#### **Format**

HeightInventory is a data. frame consisting of 4,885 observations on the 28 variables. First 26 variables are responses on scale "1" strongly disagree, "2" disagree, "3" agree, "4" strongly agree. Items 14 - 26 were reverse-coded, so that all items are scored in the same direction. Names of these items start with "Not". Original item number and English wording is provided below.

**ShortTrousers** 1. A lot of trousers are too short for me.

**TallerThanM** 2. I am taller than men of my age.

**TallerThanF** 3. I am taller than women of my age.

HeightForBasketball 4. I have an appropriate height for playing basketball or volleyball.

**AskMeToReach** 5. Other people sometimes ask me to reach something for them.

**Comments Tall** 6. I am used to hearing comments about how tall I am.

**ConcertObstructs** 7. At concerts, my stature usually obstructs other people's views.

**ShortBed** 8. Ordinary beds are too short for me.

**TopShelfEasy** 9. I can easily take wares from top shelves at a store.

**CrowdViewComf** 10. In a crowd of people, I still have a comfortable view.

**ShortBlanket** 11. Blankets and bedspreads rarely cover me completely.

**BendToHug** 12. When I want to hug someone, I usually need to bend over.

**CarefullHead** 13. I must often be careful to avoid bumping my head against a doorjamb or a low ceiling.

**NotSmallerThanM** 14. I am smaller than men of my age.

**NotStoolNeeded** 15. I often need a stool to reach something other people could reach without one.

**NotPlayDwarf** 16. I could play a dwarf.

NotSmallerThanW 17. I am smaller than women of my age.

**NotNoticeSmall** 18. One of the first things people notice about me is how small I am.

**NotOnTipToes** 19. I often need to stand on the tip of my toes to get a better view.

NotClothChildSize 20. When I buy clothes, children's sizes often fit me well.

**NotBusLegsEnoughSpace** 21. I have enough room for my legs when traveling by bus.

**NotFasterWalk** 22. I often need to walk faster than I'm used to in order to keep pace with taller people.

NotAgeUnderestim 23. Because of my smaller stature, people underestimate my age.

**NotWishLowerChair** 24. It would be more comfortable for me if chairs were made lower.

**NotUpwardLook** 25. When talking to other adults, I have to look upwards if I want to meet their eyes.

**NotMirrorTooHigh** 26. Some mirrors are placed so high up that I have to crane my neck to use them.

gender Gender membership, "M" males, "F" females.

**HeightCM** Self-reported height in centimeters.

ICCrestricted 47

# Note

Thanks to Karel Rečka and Hynek Cígler for sharing this dataset.

#### References

Rečka, K. (2018). Height and Weight Inventory. Brno, Masaryk University: Unpublished Master's thesis

**ICCrestricted** 

Range-restricted reliability with intra-class correlation

# Description

Function estimating reliability with intra-class correlation for the complete or for the range-restricted sample.

# Usage

```
ICCrestricted(
  Data,
  case,
  var,
  rank = NULL,
  dir = "top",
  sel = 1,
  nsim = 100,
  ci = 0.95,
  seed = NULL)
```

## **Arguments**

Data	matrix or data. frame which includes variables describing ID of ratees (specified in case), ratings (specified in var), and (optionally) rank of ratees (specified in rank).
case	character: name of the variable in Data with ID of the ratee (subject or object being evaluated, such as a respondent, proposal, patient, applicant etc.)
var	character: name of the variable in Data with the ratings/scores.
rank	numeric: vector of ranks of ratees. If not provided, rank of ratee is calculated based on average rating based on var variable.
dir	character: direction of range-restriction, available options are "top" (default) or "bottom". Can be an unambiguous abbreviation (i.e., "t" or "b").
sel	numeric: selected number (given > 1) or percentage (given <= 1) of ratees. Default value is 1 (complete dataset).

48 ICCrestricted

nsim numeric: number of simulations for bootstrap confidence interval. Default value

is 100.

ci numeric: confidence interval. Default value is 0.95.

seed for simulations. Default value is NULL, random seed. See lme4::bootMer()

for more detail.

#### Value

A data. frame with the following columns:

n\_sel number of ratees selected/subsetted.

prop\_sel proportion of ratees selected.

dir direction of range-restriction. NA if range is effectively not restricted (100%)

used).

VarID variance due to ratee, "true variance", between-group variance.

VarResid residual variance.
VarTotal total variance.

ICC1 single-rater inter-rater reliability.

ICC1\_LCI lower bound of the confidence interval for ICC1.

ICC1\_UCI upper bound of the confidence interval for ICC1.

ICC3 multiple-rater inter-rater reliability.

ICC3\_LCI lower bound of the confidence interval for ICC3.
ICC3\_UCI upper bound of the confidence interval for ICC3.

ItemAnalysis 49

## **Examples**

ItemAnalysis

Compute traditional item analysis indices

## Description

Computes various traditional item analysis indices including difficulty, discrimination and item validity. For ordinal items, the function returns scaled values for some of the indices. See the details below.

#### Usage

```
ItemAnalysis(
  Data,
  minscore = NULL,
  maxscore = NULL,
  cutscore = NULL,
  criterion = NULL,
  k = NULL,
  l = NULL,
  u = NULL,
  bin = "deprecated"
)
```

## **Arguments**

Data matrix or data.frame of items to be examined. Rows represent respondents,

columns represent items.

minscore, maxscore

*integer*, theoretical minimal/maximal score. If not provided, these are computed on observed data. Automatically recycled to the number of columns of the data.

cutscore integer If provided, the input data are binarized accordingly. Automatically re-

cycled to the number of columns of the data.

criterion vector of criterion values.

50 ItemAnalysis

k, 1, u Arguments passed on to gDiscrim(). Provide these if you want to compute

generalized upper-lower index along with a standard ULI (using k = 3, l = 1, u

= 3), which is provided by default.

bin *deprecated*, use cutscore instead. See the **Details**.

#### **Details**

For calculation of generalized ULI index, it is possible to specify a custom number of groups k, and which two groups 1 and u are to be compared.

In ordinal items, difficulty is calculated as difference of average score divided by range (maximal possible score maxscore minus minimal possible score minscore).

If cutscore is provided, item analysis is conducted on binarized data; values greater or equal to cut-score are set to 1, other values are set to 0. Both the minscore and maxscore arguments are then ingored and set to 0 and 1, respectively.

#### Value

A data. frame with following columns:

Difficulty average score of the item divided by its range.

Mean average item score.

SD standard deviation of the item score.

Cut.score cut-score specified in cutscore.

obs.min observed minimal score.

Min.score minimal score specified in minscore; if not provided, observed minimal score.

obs.max observed maximal score.

Max. score maximal score specified in maxscore; if not provided, observed maximal score.

Prop.max.score proportion of maximal scores.

RIT item-total correlation (correlation between item score and overall test score).

RIR item-rest correlation (correlation between item score and overall test score with-

out the given item).

ULI upper-lower index using the standard parameters (3 groups, comparing 1st and

3rd).

Corr.criterion correlation between item score and criterion criterion.

gULI generalized ULI. NA when the arguments k, 1, and u were not provided.

Alpha.drop Cronbach's alpha without given item.

Index.rel Gulliksen's (1950) item reliability index.

Gulliksen's (1950) item validity index.

Perc.miss Percentage of missed responses on the particular item.

Perc. nr Percentage of respondents that did not reached the item nor the subsequent ones,

see recode\_nr() for further details.

LearningToLearn

Dichotomous dataset of learning to learn test

#### **Description**

LearningToLearn is a real longitudinal dataset used in Martinkova et al (2020) study, demonstrating differential item functioning in change (DIF-C) on Learning to Learn (LtL) test. Among other variables, it primarily contains binary-coded responses of 782 subjects to (mostly) multiple-choice test consisting of 41 items within 7 subscales (see **Format** for details). Each respondent was tested twice in total – the first time in Grade 6 and the second time in Grade 9. Most importantly, school track (variable track\_01 or track) is available, with 391 students attending basic school (BS) and 391 pursuing selective academic school (AS). This dataset was created using propensity score matching algorithm to achieve similar characteristics in both tracks (see **References** for details). To further simplify the work with LtL dataset, we provide computed total scores as well as 7 subscores, both for Grade 6 and Grade 9. The dataset also includes *change* variables for each item (see **Format** for details) for more detailed DIF-C analysis using multinomial regression model.

#### Usage

LearningToLearn

# Format

A LearningToLearn data frame consists of 782 observations on the following 141 variables:

- track\_01 Dichotomously scored school track, where "1" denotes the selective academic school one.
- **track** School track, where "AS" represents the selective academic school track, and "BS" stands for basic school track.
- score\_6 & score\_9 Total test score value obtained by summing all 41 items of LtL, the number denotes the Grade which the respondent was taking at the time of testing.
- **score\_6\_subtest1-score\_6\_subtest7** Scores of respective cognitive subtest (1–7) of LtL in Grade 6.
- score\_9\_subtest1-score\_9\_subtest7 Scores of respective cognitive subtest (1-7) of LtL in Grade 9.
- **Item1A\_6-Item7F\_6** Dichotomously coded 41 individual items obtained at Grade 6, "1" represents the correct answer to the particular item.
- **Item1A\_9-Item7F\_9** Dichotomously coded 41 individual items obtained at Grade 9, "1" represents the correct answer to the particular item.
- Item1A\_changes-Item7F\_changes Change patterns with those possible values:

MSclinical 53

- a student responded correctly in neither Grade 6 nor in Grade 9 (did not improve, "00")
- a student responded correctly in Grade 6 but not in Grade 9 (deteriorated, "10")
- a student did not respond correctly in Grade 6 but responded correctly in Grade 9 (improved, "01"), and
- a student responded correctly in both grades (did not deteriorate, "11")

**MSclinical** 

Clinical outcomes in multiple sclerosis patients dataset

# **Description**

The MSclinical dataset contains clinical measures on multiple sclerosis patients.

#### Usage

data(MSclinical)

#### **Format**

MSclinical is a data. frame consisting of 17 observations on 13 variables.

**LCLA** Low-Contrast Letter Acuity test.

MI Motricity Index.

MAS Modified Ashworth Scale.

BBS Berg Balance Scale.

T Tremor.

**DD** Dysdiadochokinesia.

DM Dysmetria.

PRs Postural reactions.

**KH** Knee Hyperextension.

NHPT Nine-Hole Peg Test.

T25FW Timed 25-Foot Walk.

**PASAT3** 3-minute version of the Paced Auditory Serial Addition Test.

**EDSS** Kurtzke Expanded Disability Status Scale.

54 NIH

NIH

NIH grant peer review scoring dataset

## Description

The NIH dataset (Erosheva et al., 2020a) was sampled from a full set of 54,740 R01 applications submitted by black and white principal investigators (PIs) and reviewed by NIH's Center for Scientific Review (CSR) during council years 2014–2016.

It contains the original random sample of white applicants as generated by Erosheva et al. (2020b) and a sample of 46 black applicants generated to obtain the same ratio of white and black applicants as in the original sample (for details, see Erosheva et al., 2021a). The dataset was used by Erosheva et al. (2021b) to demonstrate issues of inter-rater reliability in case of restricted samples.

The available variables include preliminary criterion scores on Significance, Investigator, Innovation, Approach, Environment and a preliminary Overall Impact Score. Each of these criteria and the overall score is scored on an integer scale from 1 (best) to 9 (worst). Besides the preliminary criteria and Overall Impact Scores, the data include applicant race, the structural covariates (PI ID, application ID, reviewer ID, administering institute, IRG, and SRG), the matching variables – gender, ethnicity (Hispanic/Latino or not), career stage, type of academic degree, institution prestige (as reflected by the NIH funding bin), area of science (as reflected by the IRG handling the application), application type (new or renewal) and status (amended or not) – as well as the final overall score. In addition, the file includes a study group ID variable that refers to the Matched and Random subsets used in the original study.

#### Usage

data(NIH)

# Format

NIH is a data. frame consisting of 5802 observations on 27 variables.

**ID** Proposal ID.

**Score** Preliminary Overall Impact score (1-9 integer scale, 1 best).

**Significance, Investigator, Innovation, Approach, Environment** Preliminary Criterion Scores (1-9 integer scale, 1 best).

PIRace Principal investigator's self-identified race; "White" or "Black".

PIID Anonymized ID of principal investigator (PI).

PIGender PI's gender membership; "Male" or "Female".

PIEthn PI's ethnicity; "Hispanic/Latino" or "Non-Hispanic".

**PICareerStage** PI's career stage; "ESI" Early Stage Investigator, "Experienced" Experienced Investigator, or "Non-ES NI" Non-Early Stage New Investigator.

PIDegree PI's degree; "PhD", "MD", "MD/PhD", or "Others".

**PIInst** Lead Pl's institution's FY 2014 total institution NIH funding; 5 bins with 1 being most-funded.

nominal\_to\_int 55

GroupID Group ID.

RevID Reviewer's ID.

IRG IRG (Integrated Research Group) id.

AdminOrg Administering Organization id.

SRG SRG (Scientific Research Group) id.

**PropType** Application type, "New" or "Renewal".

Ammend Ammend. Logical.

ScoreAvg Average of the three overall scores from different reviewers.

**ScoreAvgAdj** Average of the three overall scores from different reviewers, increased by multiple of 0.001 of the worst score.

ScoreRank Project rank calculated based on ScoreAvg.

ScoreRankAdj Project rank calculated based on ScoreAvgAdj.

**ScoreFinalChar** Final Overall Impact score (1-9 integer scale, 1 best; "ND" refers to "not discussed")

**ScoreFinal** Final Overall Impact score (1-9 integer scale, 1 best).

ICCrestricted()

nominal\_to\_int

Turn nominal (factor) data to integers, keep original levels with a key of correct responses alongside

#### **Description**

Convert a data.frame or tibble with factor variables (items) to integers, keeping the original factor levels (i.e. response categories) and correct answers (stored as an key attribute of each item) alongside.

56 obtain\_nrm\_def

#### **Usage**

```
nominal_to_int(Data, key)
```

## **Arguments**

Data data.frame or tibble with all columns being factors. Support for matrix is limited

and behavior not guaranteed.

key A single-column data.frame, (not matrix) tibble or - preferably - a factor

vector of levels considered as correct responses.

#### **Details**

Fitting a nominal model using mirt::mirt() package requires the dataset to consist only of integers, *arbitrarily* representing the response categories. You can convert your dataset to integers on your own in that case.

On the other hand, BLIS model (and thus also the BLIRT parametrization) further requires the information of correct item response category. On top of that, the same information is leveraged when fitting a mirt model that conserves the "directionality" of estimated latent ability (using a model definition from obtain\_nrm\_def()). In these cases, you are recommended to use nominal\_to\_int() (note that fit\_blis() and blis() does this internally). Note also that fitted BLIS model (of class BlisClass) stores the original levels with correct answer key in its orig\_levels slot, accessible by a user via get\_orig\_levels().

#### Value

*List* of original levels with logical attribute key, which stores the information on which response (level) is considered correct. *Note that levels not used in the original data are dropped.* 

## See Also

Other BLIS/BLIRT related: BlisClass-class, coef, BlisClass-method, fit\_blis(), get\_orig\_levels(), obtain\_nrm\_def(), print.blis\_coefs()

obtain_nrm_def	Obtain model definition for mirt's nominal model taking in account
	the key of correct answers

## **Description**

Standard mirt model with itemtype = "nominal" puts the identification constrains on the item response category slopes such as  $ak_0 = 0$  and  $ak_{(K-1)} = (K-1)$ , freely estimating the rest.

While nominal item responses are unordered by definition, it is often the case that one of the item response categories is correct and the respondents endorsing this category "naturally" possess a higher latent ability. Use this function to obtain model definition where the correct response category  $k_c$  for item i with K possible response categories translates to constrains  $ak_{k_c} = (K-1)$  and  $ak_{k_{d1}} = 0$ , with  $k_{d1}$  being the first incorrect response category (i.e. the first distractor).

plot.sia\_parallel 57

#### Usage

```
obtain_nrm_def(data_with_key, ...)
```

#### **Arguments**

```
data_with_key The output of nominal_to_int().
... arguments passed onto mirt::mirt(). No practical use for now.
```

#### Value

A data.frame with the starting values, parameter numbers, estimation constrains etc. Pass it as pars argument of mirt::mirt().

#### See Also

```
Other BLIS/BLIRT related: BlisClass-class, coef, BlisClass-method, fit_blis(), get_orig_levels(), nominal_to_int(), print.blis_coefs()
```

## **Examples**

```
library(mirt)

# convert nominal data to integers and the original labels with correct answers
data_with_key <- nominal_to_int(HCItest[, 1:20], HCIkey)

# build model definition for {mirt} using the returned list from above
nrm_def <- obtain_nrm_def(data_with_key)

# fit the nominal model using the obtained model definition in `pars` argument
fit <- mirt(data_with_key$Data, 1, "nominal", pars = nrm_def)</pre>
```

plot.sia\_parallel

Plot Method for Parallel Analysis Output

# **Description**

You can call this method to plot an existing object resulting from fa\_paralell() function, which behaves as a standard data. frame, but can be automatically recognized and processed with a dedicated plot method. Also, you can *post-hoc* disable the Kaiser boundaries shown by default.

```
## S3 method for class 'sia_parallel'
plot(x, y, ...)
```

58 plotAdjacent

# **Arguments**

x object of class sia\_parallel to plot.

y ignored

... additional argument:

show\_kaiser *logical*, whether to show horizonal lines denoting Kaiser boundaries (eigenvalue 0 and/or 1 for FA and/or PCA, respectively). Defaults to TRUE.

# **Examples**

```
## Not run:
fa_parallel_result <- BFI2[, 1:60] %>% fa_parallel(plot = FALSE) # without plot
fa_parallel_result %>% plot # generate plot from "fitted" object
fa_parallel_result %>% plot(show_kaiser = FALSE) # hide Kaiser boundaries
## End(Not run)
```

plotAdjacent

Plot category probabilities of adjacent category logit model

## **Description**

Function for plotting category probabilities function estimated by vglm() function from the VGAM package using the **ggplot2** package.

# Usage

```
plotAdjacent(x, matching.name = "matching")
```

## **Arguments**

x object of class vglm matching.name character: name of matching criterion used for estimation in x.

## Value

An object of class ggplot and/or gg.

plotDIFirt

Plot item characteristic curve of DIF IRT model

# Description

Plots characteristic curve of IRT model.

plotDIFirt 61

#### Usage

```
plotDIFirt(
  parameters,
  test = "Lord",
  item = "all",
  item.name,
  same.scale = FALSE
)
```

#### **Arguments**

parameters numeric: data matrix or data frame. See **Details**.

test character: type of statistic to be shown. See **Details**.

item either character ("all"), or numeric vector, or single number corresponding to

column indicators. See Details.

item.name character: the name of item.

same.scale logical: are the item parameters on the same scale? (default is "FALSE"). See

Details.

#### **Details**

This function plots characteristic curve of DIF IRT model.

The parameters matrix has a number of rows equal to twice the number of items in the data set. The first J rows refer to the item parameter estimates in the reference group, while the last J ones correspond to the same items in the focal group. The number of columns depends on the selected IRT model: 2 for the 1PL model, 5 for the 2PL model, 6 for the constrained 3PL model and 9 for the unconstrained 3PL model. The columns of irtParam() have to follow the same structure as the output of itemParEst(), difLord() or difRaju() command from the difR package.

Two possible type of test statistics can be visualized - "Lord" gives only characteristic curves, "Raju" also highlights area between these curves.

For default option "all", all characteristic curves are plotted.

```

plotDIFLogistic

Function for characteristic curve of 2PL logistic DIF model

#### **Description**

Plots characteristic curve of 2PL logistic DIF model

# Usage

```
plotDIFLogistic(x, item = 1, item.name, group.names = c("Reference",
   "Focal"), Data, group, match, draw.empirical = TRUE)
```

#### **Arguments**

x an object of "Logistic" class. See **Details**.

item numeric: number of item to be plotted

item.name character: the name of item to be used as title of plot.

 $\mbox{group.names} \qquad \mbox{character: names of reference and focal group.}$ 

Data numeric: the data matrix. See **Details**.

group numeric: the vector of group membership. See **Details**.

match character or numeric: specifies observed score used for matching. Can be either

"score", or numeric vector of the same length as number of observations in

Data. See Details.

draw.empirical logical: whether empirical probabilities should be calculated and plotted. De-

fault value is TRUE.

plotDIFLogistic 63

#### **Details**

This function plots characteristic curves of 2PL logistic DIF model fitted by difLogistic() function from difR package using ggplot2.

Data and group are used to calculate empirical probabilities for reference and focal group. match should be the same as in x\$match. In case that an observed score is used as a matching variable instead of the total score or the standardized score, match needs to be a numeric vector of the same the same length as the number of observations in Data.

plotDistractorAnalysis
```

Plot item distractor analysis

# **Description**

Plots graphical representation of item distractor analysis with proportions and optional number of groups.

#### Usage

```
plotDistractorAnalysis(
   Data,
   key,
   num.groups = 3,
   item = 1,
   item.name,
   multiple.answers = TRUE,
   criterion = NULL,
   crit.discrete = FALSE,
   cut.points,
   data,
   matching,
   match.discrete
)
```

## **Arguments**

Data character: data matrix or data.frame with rows representing unscored item re-

sponse from a multiple-choice test and columns corresponding to the items.

key character: answer key for the items. The key must be a vector of the same length

as ncol(Data). In case it is not provided, criterion needs to be specified.

num. groups numeric: number of groups to which are the respondents splitted.

item numeric: the number of the item to be plotted.

item.name character: the name of the item.

multiple.answers

logical: should be all combinations plotted (default) or should be answers split-

ted into distractors. See **Details**.

criterion numeric: numeric vector. If not provided, total score is calculated and distractor

analysis is performed based on it.

crit.discrete logical: is criterion discrete? Default value is FALSE.

cut.points numeric: numeric vector specifying cut points of criterion.

data deprecated. Use argument Data instead.

matching deprecated. Use argument criterion instead.

match.discrete deprecated. Use argument crit.discrete instead.

#### **Details**

This function is a graphical representation of the DistractorAnalysis() function. In case that no criterion is provided, the scores are calculated using the item Data and key. The respondents are by default split into the num.groups-quantiles and the proportions of respondents in each quantile are displayed with respect to their answers. In case that criterion is discrete (crit.discrete = TRUE), criterion is split based on its unique levels. Other cut points can be specified via cut.points argument.

If multiple. answers = TRUE (default) all reported combinations of answers are plotted. If multiple. answers = FALSE all combinations are split into distractors and only these are then plotted with correct combination.

```
# loading 100-item medical admission test datasets
data(dataMedical, dataMedicaltest, dataMedicalkey)
Data <- dataMedicaltest[, 1:100]</pre>
DataBin <- dataMedical[, 1:100]</pre>
key <- dataMedicalkey
# distractor plot for items 48, 57 and 32 displaying distractors only
# correct answer B does not function well:
plotDistractorAnalysis(Data, key, item = 48, multiple.answers = FALSE)
# all options function well, thus the whole item discriminates well:
plotDistractorAnalysis(Data, key, item = 57, multiple.answers = FALSE)
# functions well, thus the whole item discriminates well:
plotDistractorAnalysis(Data, key, item = 32, multiple.answers = FALSE)
## Not run:
# distractor plot for items 48, 57 and 32 displaying all combinations
plotDistractorAnalysis(Data, key, item = c(48, 57, 32))
# distractor plot for item 57 with all combinations and 6 groups
plotDistractorAnalysis(Data, key, item = 57, num.group = 6)
# distractor plot for item 57 using specified criterion and key option
```

66 plotMultinomial

```
criterion <- round(rowSums(DataBin), -1)
plotDistractorAnalysis(Data, key, item = 57, criterion = criterion)
# distractor plot for item 57 using specified criterion without key option
plotDistractorAnalysis(Data, item = 57, criterion = criterion)
# distractor plot for item 57 using discrete criterion
plotDistractorAnalysis(Data, key,
    item = 57, criterion = criterion,
    crit.discrete = TRUE
)
# distractor plot for item 57 using groups specified by cut.points
plotDistractorAnalysis(Data, key, item = 57, cut.points = seq(10, 96, 10))
## End(Not run)</pre>
```

plotMultinomial

Plot category probabilities of multinomial model

## Description

Plots category probabilities functions estimated by multinom() from the nnet package using the **ggplot2** package.

# Usage

```
plotMultinomial(x, matching, matching.name = "matching")
```

#### **Arguments**

x object of class multinom

matching numeric: vector of matching criterion used for estimation in x. matching.name character: name of matching criterion used for estimation in x.

#### Value

An object of class ggplot and/or gg.

#### Author(s)

Adela Hladka

Institute of Computer Science of the Czech Academy of Sciences <a href="hladka@cs.cas.cz">hladka@cs.cas.cz</a>

```
nnet::multinom()
```

## **Examples**

```
# loading data
data(GMAT, GMATtest, GMATkey, package = "difNLR")

matching <- scale(rowSums(GMAT[, 1:20])) # Z-score

# multinomial model for item 1
fit <- nnet::multinom(relevel(GMATtest[, 1], ref = paste(GMATkey[1])) ~ matching)

# plotting category probabilities
plotMultinomial(fit, matching, matching.name = "Z-score")</pre>
```

plot\_corr

Compute and plot an item correlation matrix

# Description

Computes and visualizes an item correlation matrix (also known as a heatmap), offering several correlation "types" and optional clustering (with possible cluster outlining). The function relies on ggplot2() package, providing a high customisability using "the grammar of graphics" (see the examples below).

```
plot_corr(
  Data,
  cor = "pearson",
  clust_method = "none",
  n_clust = 0,
  shape = "circle",
  labels = FALSE,
  labels_size = 3,
  line_size = 0.5,
  line_col = "black",
  line_alpha = 1,
  fill = NA,
  fill_alpha = NA,
  ...
)
```

68 plot\_corr

#### **Arguments**

Data matrix, data.frame or tibble: either a data.frame with scored items (as

columns, one observation per row), or a correlation matrix.

cor character: correlation "type" used to correlation matrix computation; available

options are "poly", "tetra", "pearson", "spearman", or "none" (in case you provide the correlation matrix directly instead). You can use an unambiguous

abbreviation.

clust\_method character: optional clustering method, available options are: "ward.D", "ward.D2",

"single", "complete", "average" (= UPGMA), "mcquitty" (= WPGMA), "median" (= WPGMC), "centroid" (= UPGMC) or "none" (clustering dis-

abled). See hclust() for a detailed description of available options.

n\_clust integer: the number of clusters you want to be outlined. When set to zero,

clustering is disabled, ignoring the clust\_method argument.

shape character: tile appearance; either circle (default) to map the correlation co-

efficient to circle size and color, or square to draw square-shaped tiles with only shade denoting the coefficient magnitude. You can use an unambiguous

abbreviation of the two.

labels logical: when TRUE, the correlation coefficients are plotted onto tiles.

labels\_size numeric: label size in points (pts).
line\_size numeric: cluster outline width.

line\_col character: color of the outline, either a HEX code (e.g. "#123456"), or one of

R's standard colors (see the colors()).

line\_alpha numeric 0-1: the opacity of the outline.

fill character: the color used to fill the outlined clusters.

fill\_alpha numeric 0-1: the opacity of the fill color.

... Arguments passed on to psych::polychoric

correct Correction value to use to correct for continuity in the case of zero entry cell for tetrachoric, polychoric, polybi, and mixed.cor. See the examples for the effect of correcting versus not correcting for continuity.

smooth if TRUE and if the tetrachoric/polychoric matrix is not positive definite, then apply a simple smoothing algorithm using cor.smooth

global When finding pairwise correlations, should we use the global values of the tau parameter (which is somewhat faster), or the local values (global=FALSE)? The local option is equivalent to the polycor solution, or to doing one correlation at a time. global=TRUE borrows information for one item pair from the other pairs using those item's frequencies. This will make a difference in the presence of lots of missing data. With very small sample sizes with global=FALSE and correct=TRUE, the function will fail (for as yet underdetermined reasons.

polycor A no longer used option, kept to stop other packages from breaking. weight A vector of length of the number of observations that specifies the weights to apply to each case. The NULL case is equivalent of weights of 1 for all cases.

plot\_corr 69

std.err std.err=FALSE does not report the standard errors (faster) deprecated progress Show the progress bar (if not doing multicores)

ML ML=FALSE do a quick two step procedure, ML=TRUE, do longer maximum likelihood — very slow! Deprecated

delete Cases with no variance are deleted with a warning before proceeding. max.cat The maximum number of categories to bother with for polychoric.

#### **Details**

Correlation heatmap displays selected type of correlations between items. The color of tiles indicates how much and in which way the items are correlated - red color means positive correlation and blue color means negative correlation. Correlation heatmap can be reordered using hierarchical clustering method specified with clust\_method argument. When the desired number of clusters (argument n\_clust) is not zero and some clustering is demanded, the rectangles outlining the found clusters are drawn.

#### Value

An object of class ggplot and/or gg.

#### Author(s)

Jan Netik

Institute of Computer Science of the Czech Academy of Sciences

Patricia Martinkova

Institute of Computer Science of the Czech Academy of Sciences <martinkova@cs.cas.cz>

#### **Examples**

70 print.blis\_coefs

```
HCI %>% plot_corr(n_clust = 3) +
    ggtitle("HCI heatmap") +
    theme(legend.position = "bottom")

# mimic the look of corrplot package
plot_corr(HCI, cor = "poly", clust_method = "complete", shape = "sq") +
    scale_fill_gradient2(
    limits = c(-.1, 1),
    breaks = seq(-.1, 1, length.out = 12),
    guide = guide_colorbar(
        barheight = .8, barwidth = .0275,
        default.unit = "npc",
        title = NULL, frame.colour = "black", ticks.colour = "black"
    )
    ) + theme(axis.text = element_text(colour = "red", size = 12))

## End(Not run)
```

print.blis\_coefs

Print method for BLIS coefficients

## **Description**

Print method for BLIS coefficients

## Usage

```
## S3 method for class 'blis_coefs'
print(x, digits = 3, ...)
```

# Arguments

x result of coef().

digits integer, number of digits to show in the output. Note that printed object are still

an original list, which does not round any value (it is returned invisibly).

... Additional arguments passed on to print().

## See Also

```

```

recode\_nr 71

recode_nr	Recognize and recode not-reached responses

## **Description**

recode\_nr() function recognizes and recodes not-reached responses, i.e., missing responses to items such that all subsequent items are missed as well by the respondent.

# Usage

```
recode_nr(Data, nr_code = 99, df)
```

#### **Arguments**

Data matrix or data.frame: object to be recoded, must include only items columns

and no additional information

nr\_code single character, integer or numeric: specifying how should be recognized not-

reached responses coded (default is 99)

df deprecated. Use argument Data instead.

## Value

A data. frame object.

startShinyItemAnalysis

Start ShinyItemAnalysis application

## **Description**

An interactive shiny application to run test and item analysis. By default, the function runs the application as a background process ("Jobs" tab in the "RStudio" IDE). User is then free to use the R Console for other work and to try the sample R code examples. You can still run the app the usual way in the console by specifying background = FALSE.

#### Usage

```
startShinyItemAnalysis(background = TRUE, ...)
run_app(background = TRUE, ...)
```

#### **Arguments**

background

logical, should the application be run as a background process (in the 'RStudio')?

Arguments passed on to utils::install.packages

lib character vector giving the library directories where to install the packages. Recycled as needed. If missing, defaults to the first element of .libPaths().

repos character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as "https://cloud.r-project.org". For more details on supported URL schemes see url.

Can be NULL to install from local files, directories or URLs: this will be inferred by extension from pkgs if of length one.

contriburl URL(s) of the contrib sections of the repositories. Use this argument if your repository mirror is incomplete, e.g., because you burned only the 'contrib' section on a CD, or only have binary packages. Overrides argument repos. Incompatible with type = "both".

- method download method, see download. file. Unused if a non-NULL available is supplied.
- available a matrix as returned by available.packages listing packages available at the repositories, or NULL when the function makes an internal call to available.packages. Incompatible with type = "both".
- destdir directory where downloaded packages are stored. If it is NULL (the default) a subdirectory downloaded\_packages of the session temporary directory will be used (and the files will be deleted at the end of the session).
- dependencies logical indicating whether to also install uninstalled packages which these packages depend on/link to/import/suggest (and so on recursively). Not used if repos = NULL. Can also be a character vector, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Only supported if lib is of length one (or missing), so it is unambiguous where to install the dependent packages. If this is not the case it is ignored, with a warning.

The default, NA, means c("Depends", "Imports", "LinkingTo").

TRUE means to use c("Depends", "Imports", "LinkingTo", "Suggests") for pkgs and c("Depends", "Imports", "LinkingTo") for added dependencies: this installs all the packages needed to run pkgs, their examples, tests and vignettes (if the package author specified them correctly).

In all of these, "LinkingTo" is omitted for binary packages.

- type character, indicating the type of package to download and install. Will be "source" except on Windows and some macOS builds: see the section on 'Binary packages' for those.
- configure.args (Used only for source installs.) A character vector or a named list. If a character vector with no names is supplied, the elements are concatenated into a single string (separated by a space) and used as the value for the '--configure-args' flag in the call to R CMD INSTALL. If the character vector has names these are assumed to identify values for '--configure-args' for individual packages. This allows one to specify settings for an entire collection of packages which will be used if any of those packages are to be installed. (These settings can therefore be re-used and act as default settings.)

A named list can be used also to the same effect, and that allows multielement character strings for each package which are concatenated to a single string to be used as the value for '--configure-args'.

- configure.vars (Used only for source installs.) Analogous to configure.args for flag '--configure-vars', which is used to set environment variables for the configure run.
- clean a logical value indicating whether to add the '--clean' flag to the call to R CMD INSTALL. This is sometimes used to perform additional operations at the end of the package installation in addition to removing intermediate files.
- Ncpus the number of parallel processes to use for a parallel install of more than one source package. Values greater than one are supported if the make command specified by Sys.getenv("MAKE", "make") accepts argument -k -j Ncpus.

74 TestAnxietyCor

verbose a logical indicating if some "progress report" should be given.

INSTALL\_opts an optional character vector of additional option(s) to be passed to R CMD INSTALL for a source package install. E.g., c("--html", "--no-multiarch", "--no-test-Can also be a named list of character vectors to be used as additional options, with names the respective package names.

quiet logical: if true, reduce the amount of output. This is *not* passed to available.packages() in case that is called, on purpose.

keep\_outputs a logical: if true, keep the outputs from installing source packages in the current working directory, with the names of the output files the package names with '.out' appended. Alternatively, a character string giving the directory in which to save the outputs. Ignored when installing from local files.

#### Value

No return value. Called for side effects.

TestAnxietyCor

Correlation matrix for the test anxiety dataset

## **Description**

The TestAnxietyCor dataset contains between-item correlations for 20 items of the Test Anxiety dataset.

TestAnxietyCor 75

#### Usage

data(TestAnxietyCor)

#### **Format**

TestAnxietyCor is a data.frame consisting of between-item correlations for 20 items.

- i1 Lack of confidence during tests.
- i2 Uneasy, upset feeling.
- i3 Thinking about grades.
- i4 Freeze up.
- **i5** Thinking about getting through school.
- i6 The harder I work, the more confused I get.
- **i7** Thoughts interfere with concentration.
- i8 Jittery when taking tests.
- i9 Even when prepared, get nervous.
- i10 Uneasy before getting the test back.
- i11 Tense during test.
- i12 Exams bother me.
- i13 Tense/ stomach upset.
- i14 Defeat myself during tests.
- **i15** Panicky during tests.
- i16 Worry before important tests.
- **i17** Think about failing.
- i18 Heart beating fast during tests.
- i19 Can't stop worrying.
- i20 Nervous during test, forget facts.
