## Package 'ergm'

June 1, 2022
Version 4.2.2
Date 2022-06-01
Title Fit, Simulate and Diagnose Exponential-Family Models for Networks
Depends R (>=4.0),
network ( $>=1.17 .0$ )
Imports robustbase ( $>=0.93 .7$ ),
coda ( $>=0.19 .4$ ),
trust ( $>=0.1 .8$ ),
Matrix (>= 1.3.2),
lpSolveAPI (>= 5.5.2.0.17.7),
MASS ( $>=7.3 .53 .1$ ),
statnet.common ( $>=4.6 .0$ ),
rle ( $>=0.9 .2$ ),
purrr ( $>=0.3 .4$ ),
rlang ( $>=0.4 .10$ ),
memoise ( $>=2.0 .0$ ),
tibble ( $>=3.1 .0$ ),
magrittr ( $>=2.0 .1$ ),
parallel,
methods,
knitr,
digest,
stringr
Suggests lattice ( $>=0.20 .41$ ),
latticeExtra ( $>=0.6 .29$ ),
sna ( $>=2.6$ ),
snow ( $>=0.4 .3$ ),
latentnet ( $>=2.10 .5$ ),
rmarkdown,
Rmpi (>= 0.6.9.1),
testthat ( $>=3.0 .2$ ),
tergm ( $>=4.0 .0$ ),
ergm.count ( $>=4.0$ ),
networkDynamic ( $>=0.10 .1$ ),
withr,
covr,
Rglpk,
slam

## SystemRequirements OpenMPI

BugReports https://github.com/statnet/ergm/issues
Description An integrated set of tools to analyze and simulate networks based on exponentialfamily random graph models (ERGMs). 'ergm' is a part of the Statnet suite of packages for network analysis. See Hunter, Handcock, Butts, Goodreau, and Mor-
ris (2008) [doi:10.18637/jss.v024.i03](doi:10.18637/jss.v024.i03) and Krivitsky, Hunter, Morris, and Klumb (2021) [arXiv:2106.04997](arXiv:2106.04997).

## Description

ergm is a collection of functions to plot, fit, diagnose, and simulate from exponential-family random graph models (ERGMs). For a list of functions type: help(package='ergm')

## Details

For a complete list of the functions, use library (help="ergm") or read the rest of the manual. For a simple demonstration, use demo(packages="ergm").
When publishing results obtained using this package, please cite the original authors as described in citation(package="ergm").
All programs derived from this package must cite it. Please see the file LICENSE and http:// statnet.org/attribution.
Recent advances in the statistical modeling of random networks have had an impact on the empirical study of social networks. Statistical exponential family models (Strauss and Ikeda 1990) are a generalization of the Markov random network models introduced by Frank and Strauss (1986), which in turn derived from developments in spatial statistics (Besag, 1974). These models recognize the complex dependencies within relational data structures. To date, the use of stochastic network models for networks has been limited by three interrelated factors: the complexity of realistic models, the lack of simulation tools for inference and validation, and a poor understanding of the inferential properties of nontrivial models.
This manual introduces software tools for the representation, visualization, and analysis of network data that address each of these previous shortcomings. The package relies on the network package which allows networks to be represented in. The ergm package implements maximum likelihood estimates of ERGMs to be calculated using Markov Chain Monte Carlo (via ergm). The package also provides tools for simulating networks (via simulate.ergm) and assessing model goodness-of-fit (see mcmc.diagnostics and gof.ergm).
A number of Statnet Project packages extend and enhance ergm. These include tergm (Temporal ERGM), which provides extensions for modeling evolution of networks over time; ergm.count, which facilitates exponential family modeling for networks whose dyadic measurements are counts; and ergm.userterms, available on GitHub at https://github.com/statnet/ergm.userterms, which allows users to implement their own ERGM terms.
For detailed information on how to download and install the software, go to the ergm website: https://statnet.org. A tutorial, support newsgroup, references and links to further resources are provided there.

.dyads-ergmConstraint A meta-constraint indicating handling of arbitrary dyadic constraints

## Description

This is a flag in the proposal table indicating that the proposal can enforce arbitrary combinations of dyadic constraints. It cannot be invoked directly by the user.

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

```
absdiff-ergmTerm Absolute difference in nodal attribute
```

## Description

This term adds one network statistic to the model equaling the sum of abs(attr[i]-attr[j])^pow for all edges $(i, j)$ in the network.

```
Usage
    # binary: absdiff(attr,
    # pow=1)
    # valued: absdiff(attr,
    # pow=1,
    # form="sum")
```

## Arguments

```
attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes)
                for details.)
pow power to which to take the absolute difference
form character how to aggregate tie values in a valued ERGM
```

## Note

ergm versions 3.9.4 and earlier used different arguments for this term. See ergm-options for how to invoke the old behaviour.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
absdiffcat-ergmTerm Categorical absolute difference in nodal attribute
```

## Description

This term adds one statistic for every possible nonzero distinct value of abs(attr[i]-attr[j]) in the network. The value of each such statistic is the number of edges in the network with the corresponding absolute difference.

## Usage

```
# binary: absdiffcat(attr,
# base=NULL,
# levels=NULL)
# valued: absdiffcat(attr,
# base=NULL,
# levels=NULL,
# form="sum")
```

## Arguments

| attr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) |
| :--- | :--- |
| base | deprecated |
| levels | specifies which nonzero difference to include in or exclude from the model. (See <br> Specifying Vertex attributes and Levels (?nodal_attributes) for details.) <br> character how to aggregate tie values in a valued ERGM |
| form | che |

## Note

ergm versions 3.9.4 and earlier used different arguments for this term. See ergm-options for how to invoke the old behaviour.
The argument base is retained for backwards compatibility and may be removed in a future version. When both base and levels are passed, levels overrides base.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
altkstar-ergmTerm Alternating k-star
```

## Description

Add one network statistic to the model equal to a weighted alternating sequence of $k$-star statistics with weight parameter lambda.

## Usage

\# binary: altkstar(lambda,
\# fixed=FALSE)

## Arguments

lambda weight parameter to model
fixed indicates whether the decay parameter is fixed at the given value, or is to be fit as a curved exponential family model (see Hunter and Handcock, 2006). The default is FALSE, which means the scale parameter is not fixed and thus the model is a CEF model.

## Details

This is the version given in Snijders et al. (2006). The gwdegree and altkstar produce mathematically equivalent models, as long as they are used together with the edges (or kstar(1)) term, yet the interpretation of the gwdegree parameters is slightly more straightforward than the interpretation of the altkstar parameters. For this reason, we recommend the use of the gwdegree instead of altkstar. See Section 3 and especially equation (13) of Hunter (2007) for details.

## Note

This term can only be used with undirected networks.

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

Compute an analysis of variance table for one or more ERGM fits.

## Usage

```
## S3 method for class 'ergm'
anova(object, ..., eval.loglik = FALSE)
    ## S3 method for class 'ergmlist'
    anova(object, ..., eval.loglik = FALSE)
```

## Arguments

object, ... objects of class ergm, usually, a result of a call to ergm.
eval.loglik a logical specifying whether the log-likelihood will be evaluated if missing.

## Details

Specifying a single object gives a sequential analysis of variance table for that fit. That is, the reductions in the residual sum of squares as each term of the formula is added in turn are given in the rows of a table, plus the residual sum of squares.
The table will contain $F$ statistics (and $P$ values) comparing the mean square for the row to the residual mean square.
If more than one object is specified, the table has a row for the residual degrees of freedom and sum of squares for each model. For all but the first model, the change in degrees of freedom and sum of squares is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.
Optionally the table can include test statistics. Normally the F statistic is most appropriate, which compares the mean square for a row to the residual sum of squares for the largest model considered. If scale is specified chi-squared tests can be used. Mallows' $C_{p}$ statistic is the residual sum of squares plus twice the estimate of $\sigma^{2}$ times the residual degrees of freedom.
If any of the objects do not have estimated log-likelihoods, produces an error, unless eval. loglik=TRUE.

## Value

An object of class "anova" inheriting from class "data.frame".

## Warning

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and 's default of na.action = na.omit is used, and anova. ergmlist will detect this with an error.

## See Also

The model fitting function ergm, anova, logLik.ergm for adding the log-likelihood to an existing ergm object.

## Examples

```
data(molecule)
molecule %v% "atomic type" <- c(1,1,1,1,1,1,2,2,2,2,2,2,2,3,3,3,3,3,3,3)
fit0 <- ergm(molecule ~ edges)
anova(fit0)
fit1 <- ergm(molecule ~ edges + nodefactor("atomic type"))
anova(fit1)
fit2 <- ergm(molecule ~ edges + nodefactor("atomic type") + gwesp(0.5,
    fixed=TRUE), eval.loglik=TRUE) # Note the eval.loglik argument.
anova(fit0, fit1)
anova(fit0, fit1, fit2)
```

approx.hotelling.diff.test

Approximate Hotelling $T^{\wedge} 2$-Test for One or Two Population Means

## Description

A multivariate hypothesis test for a single population mean or a difference between them. This version attempts to adjust for multivariate autocorrelation in the samples.

## Usage

approx.hotelling.diff.test(
x ,
$y=N U L L$,
mu0 $=0$,
assume.indep = FALSE,
var. equal = FALSE,
...
)

## Arguments

x
y an optinal matrix of data values with cases in rows and variables in columns for a 2-sample test.
mu0 an optional numeric vector: for a 1-sample test, the poulation mean under the null hypothesis; and for a 2 -sample test, the difference between population means under the null hypothesis; defaults to a vector of 0 s .

$$
\begin{array}{ll}
\text { assume.indep } & \begin{array}{l}
\text { if TRUE, performs an ordinary Hotelling's test without attempting to account for } \\
\text { autocorrelation. }
\end{array} \\
\text { var. equal } & \begin{array}{l}
\text { for a 2-sample test, perform the pooled test: assume population variance-covariance } \\
\text { matrices of the two variables are equal. }
\end{array} \\
\ldots & \begin{array}{l}
\text { additional arguments, passed on to spectrum0.mvar(), etc.; in particular, order.max= } \\
\text { can be used to limit the order of the AR model used to estimate the effective } \\
\text { sample size. }
\end{array}
\end{array}
$$

## Value

An object of class htest with the following information:
statistic The $T^{2}$ statistic.
parameter Degrees of freedom.
p.value $\quad \mathrm{P}$-value.
method Method specifics.
null.value Null hypothesis mean or mean difference.
alternative Always "two.sided".
estimate Sample difference.
covariance Estimated variance-covariance matrix of the estimate of the difference.
covariance. $x \quad$ Estimated variance-covariance matrix of the estimate of the mean of $x$.
covariance.y Estimated variance-covariance matrix of the estimate of the mean of $y$.
It has a print method print. htest().

## Note

For mamc. list input, the variance for this test is estimated with unpooled means. This is not strictly correct.

## See Also

t.test()

## Description

as.network. numeric creates a random Bernoulli network of the given size as an object of class network.

## Usage

```
    ## S3 method for class 'numeric'
    as.network(
        x,
        directed = TRUE,
        hyper = FALSE,
        loops = FALSE,
        multiple = FALSE,
        bipartite = FALSE,
        ignore.eval = TRUE,
        names.eval = NULL,
        edge.check = FALSE,
        density = NULL,
        init = NULL,
        numedges = NULL,
    ...
    )
```

## Arguments

| X | count; the number of nodes in the network |
| :---: | :---: |
| directed | logical; should edges be interpreted as directed? |
| hyper | logical; are hyperedges allowed? Currently ignored. |
| loops | logical; should loops be allowed? Currently ignored. |
| multiple | logical; are multiplex edges allowed? Currently ignored. |
| bipartite | count; should the network be interpreted as bipartite? If present (i.e., nonNULL) it is the count of the number of actors in the bipartite network. In this case, the number of nodes is equal to the number of actors plus the number of events (with all actors preceding all events). The edges are then interpreted as nondirected. |
| ignore.eval | logical; ignore edge values? Currently ignored. |
| names.eval | optionally, the name of the attribute in which edge values should be stored. Currently ignored. |
| edge.check | logical; perform consistency checks on new edges? |

```
density numeric; the probability of a tie for Bernoulli networks. If neither density nor
                        init is given, it defaults to the number of nodes divided by the number of dyads
                        (so the expected number of ties is the same as the number of nodes.)
init numeric; the log-odds of a tie for Bernoulli networks. It is only used if density
                        is not specified.
numedges count; if present, sample the Bernoulli network conditional on this number of
    edges (rather than independently with the specified probability).
... additional arguments
```

## Details

The network will not have vertex, edge or network attributes. These can be added with operators such as \%v\%, \%n\%, \%e\%.

## Value

An object of class network

network

## Examples

```
#Draw a random directed network with 25 nodes
g<-network(25)
#Draw a random undirected network with density 0.1
g<-network(25, directed=FALSE, density=0.1)
#Draw a random bipartite network with 4 actors and 6 events and density 0.1
g<-network(10, bipartite=4, density=0.1)
```

```
asymmetric-ergmTerm Asymmetric dyads
```

## Description

This term adds one network statistic to the model equal to the number of pairs of actors for which exactly one of $(i \rightarrow j)$ or $(j \rightarrow i)$ exists.

## Usage

\# binary: asymmetric(attr=NULL, diff=FALSE, keep=NULL, levels=NULL)

## Arguments

| attr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) If specified, only symmetric pairs that match on the vertex attribute <br> are counted. |
| :--- | :--- |
| diff | Used in the same way as for the nodematch term. (See nodematch (?nodematch) <br> for details.) |
| keep | deprecated <br> level |
| Used in the same way as for the nodematch term. (See nodematch (?nodematch) <br> for details.) |  |

Note
This term can only be used with directed networks.
The argument keep is retained for backwards compatibility and may be removed in a future version. When both keep and levels are passed, levels overrides keep.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
atleast-ergmTerm Number of dyads with values greater than or equal to a threshold
```

## Description

Adds the number of statistics equal to the length of threshold equaling to the number of dyads whose values equal or exceed the corresponding element of threshold.

## Usage

\# valued: atleast(threshold=0)

## Arguments

threshold vector of numerical values

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

Adds the number of statistics equal to the length of threshold equaling to the number of dyads whose values equal or are exceeded by the corresponding element of threshold.

## Usage

\# valued: atmost(threshold=0)

## Arguments

threshold a vector of numerical values

## See Also

ergmTerm for index of model terms currently visible to the package.

```
attrcov-ergmTerm Edge covariate by attribute pairing
```

## Description

This term adds one statistic to the model, equal to the sum of the covariate values for each edge appearing in the network, where the covariate value for a given edge is determined by its mixing type on attr. Undirected networks are regarded as having undirected mixing, and it is assumed that mat is symmetric in that case.
This term can be useful for simulating large networks with many mixing types, where nodemix would be slow due to the large number of statistics, and edgecov cannot be used because an adjacency matrix would be too big.

## Usage

\# binary: attrcov(attr, mat)

## Arguments

attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.)
mat a matrix of covariates with the same dimensions as a mixing matrix for attr

## See Also

ergmTerm for index of model terms currently visible to the package.

B-ergmTerm Wrap binary terms for use in valued models

## Description

Wraps binary ergm terms for use in valued models, with formula specifying which terms are to be wrapped and form specifying how they are to be used and how the binary network they are evaluated on is to be constructed.

## Usage

\# valued: $B$ (formula, form)

## Arguments

formula a one-sided ergm()-style formula whose RHS contains the binary ergm terms to be evaluated. Which terms may be used depends on the argument form
form One of three values:

- "sum": see section "Generalizations of binary terms" in ergmTerm help; all terms in formula must be dyad-independent.
- "nonzero": section "Generalizations of binary terms" in ergmTerm help; any binary ergm terms may be used in formula.
- a one-sided formula value-dependent network. form must contain one "valued" ergm term, with the following properties:
- dyadic independence;
- dyadwise contribution of either 0 or 1 ; and
- dyadwise contribution of 0 for a 0 -valued dyad.

Formally, this means that it is expressable as

$$
g(y)=\sum_{i, j} f_{i, j}\left(y_{i, j}\right)
$$

where for all $i, j$, and $y, f_{i, j}\left(y_{i, j}\right)$ is either 0 or 1 and, in particular, $f_{i, j}(0)=$ 0 .
Examples of such terms include nonzero, ininterval(), atleast(), atmost(), greaterthan(), lessthen(), and equalto().
Then, the value of the statistic will be the value of the statistics in formula evaluated on a binary network that is defined to have an edge if and only if the corresponding dyad of the valued network adds 1 to the valued term in form.

## Details

For example, B(~nodecov("a"), form="sum") is equivalent to nodecov("a", form="sum") and similarly with form="nonzero".
When a valued implementation is available, it should be preferred, as it is likely to be faster.

## See Also

ergmTerm for index of model terms currently visible to the package.
b1 concurrent-ergmTerm Concurrent node count for the first mode in a bipartite network

## Description

This term adds one network statistic to the model, equal to the number of nodes in the first mode of the network with degree 2 or higher. The first mode of a bipartite network object is sometimes known as the "actor" mode. This term can only be used with undirected bipartite networks.

## Usage

\# binary: b1concurrent(by=NULL, levels=NULL)

## Arguments

| by | optional argument specifying a vertex attribute (see Specifying Vertex attributes <br> and Levels (?nodal_attributes) for details). It functions just like the by ar- <br> gument of the b1degree term. Without the optional argument, this statistic is <br> equivalent to b1mindegree(2) . |
| :--- | :--- |
| levels | TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for <br> details.) |

## See Also

ergmTerm for index of model terms currently visible to the package.

$$
\text { b1cov-ergmTerm } \quad \text { Main effect of a covariate for the first mode in a bipartite network }
$$

## Description

This term adds a single network statistic for each quantitative attribute or matrix column to the model equaling the total value of $\operatorname{attr}(\mathrm{i})$ for all edges /eqn $(i, j)$ in the network. This term may only be used with bipartite networks. For categorical attributes, see b1factor .

## Usage

\# binary: b1cov(attr)
\# valued: b1cov(attr, form="sum")

## Arguments

```
attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes)
                                for details.)
    form character how to aggregate tie values in a valued ERGM
```

## Note

ergm versions 3.9.4 and earlier used different arguments for this term. See ergm-options for how to invoke the old behaviour.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
b1degrange-ergmTerm Degree range for the first mode in a bipartite network
```

## Description

This term adds one network statistic to the model for each element of from (or to ); the $i$ th such statistic equals the number of nodes of the first mode ("actors") in the network of degree greater than or equal to from[i] but strictly less than to[i], i.e. with edge count in semiopen interval [from,to).

This term can only be used with bipartite networks; for directed networks see idegrange and odegrange . For undirected networks, see degrange, and see b2degrange for degrees of the second mode ("events").

## Usage

\# binary: b1degrange(from, to=`+Inf`, by=NULL, homophily=FALSE, levels=NULL)

## Arguments

from, to vectors of distinct integers. If one of the vectors have length 1 , it is recycled to the length of the other. Otherwise, it must have the same length.
by, homophily the optional argument by specifies a vertex attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details). If this is specified and homophily is TRUE, then degrees are calculated using the subnetwork consisting of only edges whose endpoints have the same value of the by attribute. If by is specified and homophily is FALSE (the default), then separate degree range statistics are calculated for nodes having each separate value of the attribute.
levels TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)

## See Also

ergmTerm for index of model terms currently visible to the package.
b1degree-ergmTerm Degree for the first mode in a bipartite network

## Description

This term adds one network statistic to the model for each element in d ; the $i$ th such statistic equals the number of nodes of degree $\mathrm{d}[\mathrm{i}]$ in the first mode of a bipartite network, i.e. with exactly $\mathrm{d}[\mathrm{i}]$ edges. The first mode of a bipartite network object is sometimes known as the "actor" mode.

## Usage

\# binary: b1degree(d, by=NULL, levels=NULL)

## Arguments

d
by a vertex attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details). If this is specified then each node's degree is tabulated only with other nodes having the same value of the by attribute.
levels TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)

Note
This term can only be used with undirected bipartite networks.

## See Also

ergmTerm for index of model terms currently visible to the package.

## b1degrees-ergmConstraint

Preserve the actor degree for bipartite networks

## Description

For bipartite networks, preserve the degree for the first mode of each vertex of the given network, while allowing the degree for the second mode to vary.

## Usage

\# b1degrees

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

## Description

This term adds one network statistic to the model for each element in d; the $i$ th such statistic equals the number of dyads in the first bipartition with exactly $d[i]$ shared partners. (Those shared partners, of course, must be members of the second bipartition.) This term can only be used with bipartite networks.

## Usage

\# binary: b1dsp(d)

## Arguments

d
a vector of distinct integers.

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

This term adds multiple network statistics to the model, one for each of (a subset of) the unique values of the attr attribute. Each of these statistics gives the number of times a node with that attribute in the first mode of the network appears in an edge. The first mode of a bipartite network object is sometimes known as the "actor" mode.

## Usage

\# binary: b1factor(attr, base=1, levels=-1)
\# valued: b1factor(attr, base=1, levels=-1, form="sum")

## Arguments

| attr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) <br> deprecated |
| :--- | :--- |
| base | this optional argument controls which levels of the attribute attributes and Levels <br> (?nodal_attributes) for details.) <br> character how to aggregate tie values in a valued ERGM |
| form | chat |

## Note

To include all attribute values is usually not a good idea, because the sum of all such statistics equals the number of edges and hence a linear dependency would arise in any model also including edges. The default, levels=-1, is therefore to omit the first (in lexicographic order) attribute level. To include all levels, pass either levels=TRUE (i.e., keep all levels) or levels=NULL (i.e., do not filter levels).

The argument base is retained for backwards compatibility and may be removed in a future version. When both base and levels are passed, levels overrides base.

This term can only be used with undirected bipartite networks.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
b1mindegree-ergmTerm Minimum degree for the first mode in a bipartite network
```

## Description

This term adds one network statistic to the model for each element in d ; the $i$ th such statistic equals the number of nodes in the first mode of a bipartite network with at least degree $\mathrm{d}[\mathrm{i}]$. The first mode of a bipartite network object is sometimes known as the "actor" mode.

## Usage

\# binary: b1mindegree(d)

## Arguments

d a vector of distinct integers.

## Note

This term can only be used with undirected bipartite networks.

## See Also

ergmTerm for index of model terms currently visible to the package.

## b1nodematch-ergmTerm Nodal attribute-based homophily effect for the first mode in a bipartite network

## Description

This term is introduced in Bomiriya et al (2014). With the default alpha and beta values, this term will simply be a homophily based two-star statistic. This term adds one statistic to the model unless diff is set to TRUE, in which case the term adds multiple network statistics to the model, one for each of (a subset of) the unique values of the attr attribute.

## Usage

```
    # binary: b1nodematch(attr, diff=FALSE, keep=NULL, alpha=1, beta=1, byb2attr=NULL,
    # levels=NULL)
```

## Arguments

| attr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) <br> by default, one statistic will be added to the model. If diff is set to TRUE, one <br> statistic will be added for each unique value of the attr attribute <br> deprecated |
| :--- | :--- |
| diff | optional discount parameters both of which take values from [0, 1], only one <br> should be set at one time |
| alpha, beta |  |
| byb2attr | specifies a second mode categorical attribute. Setting this argument will separate <br> the orginal statistics based on the values of the set second mode attribute- i.e. <br> for example, if diff is FALSE, then the sum of all the statistics for each level <br> of this second-mode attribute will be equal to the original b1nodematch statistic <br> where byb2attr set to NULL. |
| levels | select a subset of attr values to include. (See Specifying Vertex attributes and <br> Levels (?nodal_attributes) for details.) |

## Details

If an alpha discount parameter is used, each of these statistics gives the sum of the number of common second-mode nodes raised to the power alpha for each pair of first-mode nodes with that attribute. If a beta discount parameter is used, each of these statistics gives half the sum of the number of two-paths with two first-mode nodes with that attribute as the two ends of the two path raised to the power beta for each edge in the network.

## Note

This term can only be used with undirected bipartite networks.
The argument keep is retained for backwards compatibility and may be removed in a future version. When both keep and levels are passed, levels overrides keep.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
b1sociality-ergmTerm Degree
```

## Description

This term adds one network statistic for each node in the first bipartition, equal to the number of ties of that node. This term can only be used with bipartite networks. For directed networks, see sender and receiver. For unipartite networks, see sociality.

## Usage

\# binary: b1sociality(nodes=-1)
\# valued: b1sociality(nodes=-1, form="sum")

## Arguments

nodes By default, nodes $=-1$ means that the statistic for the first node (in the second bipartition) will be omitted, but this argument may be changed to control which statistics are included. The nodes argument is interpreted using the new UI for level specification (see Specifying Vertex Attributes and Levels (?nodal_attributes) for details), where both the attribute and the sorted unique values are the vector of vertex indices $(n b 1+1): n$, where $n b 1$ is the size of the first bipartition and n is the total number of nodes in the network. Thus nodes $=120$ will include only the statistic for the 120th node in the second biparition, while nodes $=\mathrm{I}$ (120) will include only the statistic for the 120th node in the entire network.
form character how to aggregate tie values in a valued ERGM

## See Also

ergmTerm for index of model terms currently visible to the package.
b1star-ergmTerm $\quad k$-Stars for the first mode in a bipartite network

## Description

This term adds one network statistic to the model for each element in k . The $i$ th such statistic counts the number of distinct $\mathrm{k}[\mathrm{i}]$-stars whose center node is in the first mode of the network. The first mode of a bipartite network object is sometimes known as the "actor" mode. A $k$-star is defined to be a center node $N$ and a set of $k$ different nodes $\left\{O_{1}, \ldots, O_{k}\right\}$ such that the ties $\left\{N, O_{i}\right\}$ exist for $i=1, \ldots, k$. If args is specified then the count is over the number of $k$-stars (with center node in the first mode) where all nodes have the same value of the attribute. This term can only be used for undirected bipartite networks.

## Usage

\# binary: b1star(k, attr=NULL, levels=NULL)

## Arguments

| k | a vector of distinct integers |
| :--- | :--- |
| attr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) |
| levels | TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for <br> details.) |

## Note

b1star(1) is equal to b2star(1) and to edges .

## See Also

ergmTerm for index of model terms currently visible to the package.

$$
\begin{array}{ll}
\text { b1starmix-ergmTerm } & \begin{array}{l}
\text { Mixing matrix for } k \text {-stars centered on the first mode of a bipartite net- } \\
\text { work }
\end{array}
\end{array}
$$

## Description

This term counts all k-stars in which the b2 nodes (called events in some contexts) are homophilous in the sense that they all share the same value of attr. However, the b1 node (in some contexts, the actor) at the center of the k-star does NOT have to have the same value as the b2 nodes; indeed, the values taken by the b1 nodes may be completely distinct from those of the b2 nodes, which allows for the use of this term in cases where there are two separate nodal attributes, one for the b1 nodes and another for the b2 nodes (in this case, however, these two attributes should be combined to form a single nodal attribute, attr ). A different statistic is created for each value of attr seen in a b1 node, even if no k-stars are observed with this value.

## Usage

\# binary: b1starmix(k, attr, base=NULL, diff=TRUE)

## Arguments

k
attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.)
base deprecated
diff whether a different statistic is created for each value seen in a b2 node. When diff=TRUE, the default, a different statistic is created for each value and thus the behavior of this term is reminiscent of the nodemix term, from which it takes its name; when diff=FALSE, all homophilous k-stars are counted together, though these k -stars are still categorized according to the value of the central b1 node.

## Note

The argument base is retained for backwards compatibility and may be removed in a future version. When both base and levels are passed, levels overrides base.

## See Also

ergmTerm for index of model terms currently visible to the package.

$$
\begin{array}{ll}
\text { b1twostar-ergmTerm } & \begin{array}{l}
\text { Two-star census for central nodes centered on the first mode of a bi- } \\
\text { partite network }
\end{array}
\end{array}
$$

## Description

This term takes two nodal attributes. Assuming that there are $n_{1}$ values of b1attr among the b1 nodes and $n_{2}$ values of b2attr among the b2 nodes, then the total number of distinct categories of two stars according to these two attributes is $n_{1}\left(n_{2}\right)\left(n_{2}+1\right) / 2$. By default, this model term creates a distinct statistic counting each of these categories.

## Usage

\# binary: b1twostar(b1attr, b2attr, base=NULL, b1levels=NULL, b2levels=NULL, levels2=NULL)

## Arguments

b1attr b1 nodes (actors in some contexts) (see Specifying Vertex attributes and Levels (?nodal_attributes) for details)
b2attr b2 nodes (events in some contexts). If b2attr is not passed, it is assumed to be the same as b1attr.
b1levels, b2levels, base, levels2
used to leave some of the categories out (see Specifying Vertex attributes and Levels (?nodal_attributes) for details)

## Note

The argument base is retained for backwards compatibility and may be removed in a future version. When both base and levels are passed, levels overrides base.

The argument base is retained for backwards compatibility and may be removed in a future version. When both base and levels2 are passed, levels2 overrides base.

## See Also

ergmTerm for index of model terms currently visible to the package.
b2concurrent-ergmTerm Concurrent node count for the second mode in a bipartite network

## Description

This term adds one network statistic to the model, equal to the number of nodes in the second mode of the network with degree 2 or higher. The second mode of a bipartite network object is sometimes known as the "event" mode. Without the optional argument, this statistic is equivalent to b2mindegree(2).

## Usage

\# binary: b2concurrent(by=NULL)

## Arguments

by
This optional argument specifie a vertex attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details); it functions just like the by argument of the b2degree term.

## Note

This term can only be used with undirected bipartite networks.

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

This term adds a single network statistic for each quantitative attribute or matrix column to the model equaling the total value of $\operatorname{attr}(\mathrm{j})$ for all edges $(i, j)$ in the network. This term may only be used with bipartite networks. For categorical attributes, see b2factor.

## Usage

\# binary: b2cov(attr)
\# valued: b2cov(attr, form="sum")

## Arguments

attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.)
form character how to aggregate tie values in a valued ERGM

Note
ergm versions 3.9.4 and earlier used different arguments for this term. See ergm-options for how to invoke the old behaviour.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
b2degrange-ergmTerm Degree range for the second mode in a bipartite network
```

## Description

This term adds one network statistic to the model for each element of from (or to ); the $i$ th such statistic equals the number of nodes of the second mode ("events") in the network of degree greater than or equal to from[i] but strictly less than to[i], i.e. with edge count in semiopen interval [from, to).
This term can only be used with bipartite networks; for directed networks see idegrange and odegrange. For undirected networks, see degrange, and see b1degrange for degrees of the first mode ("actors").

## Usage

\# binary: b2degrange(from, to=+Inf, by=NULL, homophily=FALSE, levels=NULL)

## Arguments

$$
\begin{array}{ll}
\text { from, to } & \begin{array}{l}

\text { details.) }
\end{array}
\end{array}
$$

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

This term adds one network statistic to the model for each element in d ; the $i$ th such statistic equals the number of nodes of degree $\mathrm{d}[\mathrm{i}]$ in the second mode of a bipartite network, i.e. with exactly $\mathrm{d}[\mathrm{i}]$ edges. The second mode of a bipartite network object is sometimes known as the "event" mode.

## Usage

\# binary: b2degree(d, by=NULL)

## Arguments

d
by this optional term specifies a vertex attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details). If this is specified then each node's degree is tabulated only with other nodes having the same value of the by attribute.

## Note

This term can only be used with undirected bipartite networks.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
b2degrees-ergmConstraint
```

    Preserve the receiver degree for bipartite networks
    
## Description

For bipartite networks, preserve the degree for the second mode of each vertex of the given network, while allowing the degree for the first mode to vary.

## Usage

\# b2degrees

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.
b2dsp-ergmTerm Dyadwise shared partners for dyads in the second bipartition

## Description

This term adds one network statistic to the model for each element in d ; the $i$ th such statistic equals the number of dyads in the second bipartition with exactly $d[i]$ shared partners. (Those shared partners, of course, must be members of the first bipartition.) This term can only be used with bipartite networks.

## Usage

\# binary: b2dsp(d)

## Arguments

d
a vector of distinct integers

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

This term adds multiple network statistics to the model, one for each of (a subset of) the unique values of the attr attribute. Each of these statistics gives the number of times a node with that attribute in the second mode of the network appears in an edge. The second mode of a bipartite network object is sometimes known as the "event" mode.

## Usage

\# binary: b2factor(attr, base=1, levels=-1)
\# valued: b2factor(attr, base=1, levels=-1, form="sum")

## Arguments

attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.)
base deprecated
levels this optional argument controls which levels of the attribute attributes and Levels (?nodal_attributes) for details.)
form character how to aggregate tie values in a valued ERGM

## Note

To include all attribute values is usually not a good idea, because the sum of all such statistics equals the number of edges and hence a linear dependency would arise in any model also including edges. The default, levels=-1, is therefore to omit the first (in lexicographic order) attribute level. To include all levels, pass either levels=TRUE (i.e., keep all levels) or levels=NULL (i.e., do not filter levels).

The argument base is retained for backwards compatibility and may be removed in a future version. When both base and levels are passed, levels overrides base.

This term can only be used with undirected bipartite networks.

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

This term adds one network statistic to the model for each element in d ; the $i$ th such statistic equals the number of nodes in the second mode of a bipartite network with at least degree $d[i]$. The second mode of a bipartite network object is sometimes known as the "event" mode.

## Usage

\# binary: b2mindegree(d)

## Arguments

d
a vector of distinct integers

## Note

This term can only be used with undirected bipartite networks.

## See Also

ergmTerm for index of model terms currently visible to the package.

b2nodematch-ergmTerm | Nodal attribute-based homophily effect for the second mode in a bi- |
| :--- |
| partite network |

## Description

This term is introduced in Bomiriya et al (2014). With the default alpha and beta values, this term will simply be a homophily based two-star statistic. This term adds one statistic to the model unless diff is set to TRUE, in which case the term adds multiple network statistics to the model, one for each of (a subset of) the unique values of the attr attribute.

## Usage

\# binary: b2nodematch(attr, diff=FALSE, keep=NULL, alpha=1, beta=1, byb1attr=NULL, \# levels=NULL)

## Arguments

| diff | by default, one statistic will be added to the model. If diff is set to TRUE, one <br> statistic will be added for each unique value of the attr attribute |
| :--- | :--- |
| keep | deprecated <br> alpha, beta <br> optional discount parameters both of which take values from [0, 1], only one <br> should be set at one time |
| byb2attr | specifies a second mode categorical attribute. Setting this argument will separate <br> the orginal statistics based on the values of the set second mode attribute- i.e. <br> for example, if diff is FALSE, then the sum of all the statistics for each level <br> of this second-mode attribute will be equal to the original b1nodematch statistic <br> where byb2attr set to NULL . |
| levels | select a subset of attr values to include. (See Specifying Vertex attributes and <br> Levels (?nodal_attributes) for details.) |
| attr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) |

## Details

If an alpha discount parameter is used, each of these statistics gives the sum of the number of common first-mode nodes raised to the power alpha for each pair of second-mode nodes with that attribute. If a beta discount parameter is used, each of these statistics gives half the sum of the number of two-paths with two second-mode nodes with that attribute as the two ends of the two path raised to the power beta for each edge in the network.

## Note

This term can only be used with undirected bipartite networks.
The argument keep is retained for backwards compatibility and may be removed in a future version. When both keep and levels are passed, levels overrides keep.

## See Also

ergmTerm for index of model terms currently visible to the package.
b2sociality-ergmTerm Degree

## Description

This term adds one network statistic for each node in the second bipartition, equal to the number of ties of that node. For directed networks, see sender and receiver. For unipartite networks, see sociality.

## Usage

\# binary: b2sociality(nodes=-1)
\# valued: b2sociality(nodes=-1, form="sum")

## Arguments

$$
\begin{aligned}
& \text { nodes } \begin{array}{l}
\text { By default, nodes }=-1 \text { means that the statistic for the first node (in the sec- } \\
\text { ond bipartition) will be omitted, but this argument may be changed to con- } \\
\text { trol which statistics are included. The nodes argument is interpreted using } \\
\text { the new UI for level specification (see Specifying Vertex Attributes and Lev- } \\
\text { els (?nodal_attributes) for details), where both the attribute and the sorted } \\
\text { unique values are the vector of vertex indices (nb1 }+1 \text { ): } n \text {, where nb1 is the } \\
\text { size of the first bipartition and } n \text { is the total number of nodes in the network. } \\
\text { Thus nodes }=120 \text { will include only the statistic for the } 120 \text { th node in the second } \\
\text { biparition, while nodes }=\mathrm{I}(120) \text { will include only the statistic for the 120th node } \\
\text { in the entire network. } \\
\text { form }
\end{array} \text { character how to aggregate tie values in a valued ERGM }
\end{aligned}
$$

## Note

This term can only be used with undirected bipartite networks.

## See Also

ergmTerm for index of model terms currently visible to the package.
b2star-ergmTerm $\quad k$-Stars for the second mode in a bipartite network

## Description

This term adds one network statistic to the model for each element in k . The $i$ th such statistic counts the number of distinct $\mathrm{k}[\mathrm{i}]$-stars whose center node is in the second mode of the network. The second mode of a bipartite network object is sometimes known as the "event" mode. A $k$-star is defined to be a center node $N$ and a set of $k$ different nodes $\left\{O_{1}, \ldots, O_{k}\right\}$ such that the ties $\left\{N, O_{i}\right\}$ exist for $i=1, \ldots, k$. This term can only be used for undirected bipartite networks.

## Usage

\# binary: b2star(k, attr=NULL, levels=NULL)

## Arguments

k
attr
levels
a vector of distinct integers
quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.) then the count is over the number of $k$-stars (with center node in the second mode) where all nodes have the same value of the attribute.
TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)

## Note

b2star(1) is equal to b1star(1) and to edges.

## See Also

ergmTerm for index of model terms currently visible to the package.

$$
\begin{array}{ll}
\text { b2starmix-ergmTerm } & \begin{array}{l}
\text { Mixing matrix for } k \text {-stars centered on the second mode of a bipartite } \\
\text { network }
\end{array}
\end{array}
$$

## Description

This term is exactly the same as b1starmix except that the roles of b1 and b2 are reversed.

## Usage

\# binary: b2starmix(k, attr, base=NULL, diff=TRUE)

## Arguments

$\begin{array}{ll}\mathrm{k} & \text { only a single value of } k \text { is allowed } \\ \text { attr } & \begin{array}{l}\text { quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) } \\ \text { for details.) } \\ \text { deprecated }\end{array} \\ \text { base } & \begin{array}{l}\text { whether a different statistic is created for each value seen in a b1 node. When } \\ \text { diff=TRUE, the default, a different statistic is created for each value and thus the } \\ \text { behavior of this term is reminiscent of the nodemix term, from which it takes its } \\ \text { name; when diff=FALSE, all homophilous k-stars are counted together, though } \\ \text { these k-stars are still categorized according to the value of the central b1 node. }\end{array}\end{array}$

## Note

The argument base is retained for backwards compatibility and may be removed in a future version. When both base and levels are passed, levels overrides base.

## See Also

ergmTerm for index of model terms currently visible to the package.
b2twostar-ergmTerm Two-star census for central nodes centered on the second mode of a bipartite network

## Description

This term is exactly the same as b1twostar except that the roles of b1 and b2 are reversed.

## Usage

\# binary: b2twostar(b1attr, b2attr, base=NULL, b1levels=NULL, b2levels=NULL, levels2=NULL)

## Arguments

| b1attr | b1 nodes (actors in some contexts) (see Specifying Vertex attributes and Levels <br> (?nodal_attributes) for details) |
| :--- | :--- |
| b2attr | b2 nodes (events in some contexts). If b1attr is not passed, it is assumed to be <br> the same as b2attr |
| b1levels, b2levels, base, levels2 |  |
| used to leave some of the categories out (see Specifying Vertex attributes and |  |
| Levels (?nodal_attributes) for details) |  |

## Note

The argument base is retained for backwards compatibility and may be removed in a future version. When both base and levels are passed, levels overrides base.

The argument base is retained for backwards compatibility and may be removed in a future version. When both base and levels2 are passed, levels2 overrides base.

## See Also

ergmTerm for index of model terms currently visible to the package.
balance-ergmTerm Balanced triads

## Description

This term adds one network statistic to the model equal to the number of triads in the network that are balanced. The balanced triads are those of type 102 or 300 in the categorization of Davis and Leinhardt (1972). For details on the 16 possible triad types, see ?triad.classify in the \{sna\} package. For an undirected network, the balanced triads are those with an odd number of ties (i.e., 1 and 3).

## Usage

\# binary: balance

## See Also

ergmTerm for index of model terms currently visible to the package.
bd-ergmConstraint Constrain maximum and minimum vertex degree

## Description

Condition on the number of inedge or outedges posessed by a node. See Placing Bounds on Degrees section for more information. (?ergmConstraint)

## Usage

\# bd(attribs, maxout, maxin, minout, minin)

## Arguments

attribs a matrix of logicals with dimension (n_nodes, attrcount) for the attributes on which we are conditioning, where attrcount is the number of distinct attributes values to condition on.
maxout, maxin, minout, minin
matrices of alter attributes with the same dimension as attribs when used in conjunction with attribs. Otherwise, vectors of integers specifying the relevant limits. If the vector is of length 1 , the limit is applied to all nodes. If an individual entry is NA, then there is no restriction of that kind is applied.

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

```
Bernoulli-ergmReference
```

    Bernoulli reference
    
## Description

Specifies each dyad's baseline distribution to be Bernoulli with probability of the tie being 0.5 . This is the only reference measure used in binary mode.

## Usage

\# Bernoulli

## See Also

ergmReference for index of reference distributions currently visible to the package.

```
blockdiag-ergmConstraint
```

Force a block-diagonal structure on the network

## Description

Only dyads $(i, j)$ for which attr(i)==attr( j$)$ can have edges.
Note that the current implementation requires that blocks be contiguous for unipartite graphs, and for bipartite graphs, they must be contiguous within a partition and must have the same ordering in both partitions. (They do not, however, require that all blocks be represented in both partitions, but those that overlap must have the same order.)

If multiple block-diagonal constraints are given, or if attr is a vector with multiple attribute names, blocks will be constructed on all attributes matching.

## Usage

\# blockdiag(attr)

## Arguments

attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.)

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

```
blocks-ergmConstraint Constrain "blocks" of dyads
```

## Description

Any dyad whose toggle would produce a nonzero change statistic for a nodemix term with the same arguments will be fixed. Note that the levels2 argument has a different default value for blocks than it does for nodemix .

## Usage

\# blocks(attr=NULL, levels=NULL, levels2=FALSE, b1levels=NULL, b2levels=NULL)

## Arguments

attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.)
b1levels, b2levels, levels, level2
control what statistics are included in the model and the order in which they appear. levels2 apply to all networks; levels applies to unipartite networks; b1levels and b2levels apply to bipartite networks (see Specifying Vertex attributes and Levels (?nodal_attributes) for details)

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

```
check.ErgmTerm Ensures an Ergm Term and its Arguments Meet Appropriate Condi-
    tions
```

## Description

Helper functions for implementing ergm() terms, to check whether the term can be used with the specified network. For information on ergm terms, see ergmTerm. ergm. checkargs, ergm. checkbipartite, and ergm. checkderected are helper functions for an old API and are deprecated. Use check.ErgmTerm.

## Usage

check.ErgmTerm(
nw,
arglist,
directed = NULL,
bipartite = NULL,
nonnegative $=$ FALSE,
varnames = NULL,
vartypes = NULL,
defaultvalues = list(),
required $=$ NULL,
dep.inform = rep(FALSE, length(required)),
dep.warn $=\operatorname{rep}(F A L S E$, length(required)),
argexpr = NULL
)

## Arguments

nw
arglist
directed
bipartite
the network that term X is being checked against
the list of arguments for term X
logical, whether term X requires a directed network; default=NULL
whether term X requires a bipartite network ( T or F ); default=NULL

| nonnegative | whether term X requires a network with only nonnegative weights; default=FALSE |
| :---: | :---: |
| varnames | the vector of names of the possible arguments for term X; default=NULL |
| vartypes | the vector of types of the possible arguments for term X, separated by commas; an empty string ("") or NA disables the check for that argument, and also see Details; default=NULL |
| defaultvalues | the list of default values for the possible arguments of term X; default=list() |
| required | the logical vector of whether each possible argument is required; default=NULL |
| dep.inform, dep.warn |  |
|  | a list of length equal to the number of arguments the term can take; if the corresponding element of the list is not FALSE, a message() or a warning() respectively will be issued if the user tries to pass it; if the element is a character string, it will be used as a suggestion for replacement. |
| argexpr | optional call typically obtained by calling substitute(arglist). |

## Details

The check.ErgmTerm function ensures for the InitErgmTerm. X function that the term X :

- is applicable given the 'directed' and 'bipartite' attributes of the given network
- is not applied to a directed bipartite network
- has an appropiate number of arguments
- has correct argument types if arguments where provided
- has default values assigned if defaults are available
by halting execution if any of the first 3 criteria are not met.
As a convenience, if an argument is optional and its default is NULL, then NULL is assumed to be an acceptable argument type as well.

## Value

A list of the values for each possible argument of term $X$; user provided values are used when given, default values otherwise. The list also has an attr(,"missing") attribute containing a named logical vector indicating whether a particular argument had been set to its default. If argexpr= argument is provided, attr (, "exprs") attribute is also returned, containing expressions.

## cohab

## Description

This dataset consists of three objects, each based on data from King County, Washington, USA (where Seattle is located) derived from the National Survey of Family Growth (NSFG) (https: //www.cdc.gov/nchs/nsfg/index.htm). The full dataset cannot be released publicly, so some aspects of these objects are simulated based on the real data. These objects may be used to illustrate that network modeling may be performed using data that are collected on egos only, i.e., without directly observing information about alters in a network except for information reported from egos. The hypothetical population reepresented by this dataset consists of only a subset of individuals, as categorized by their age, race / ethnicity / immigration status, and gender and sexual identity.

## Usage

data(cohab)

## Details

The three objects are
cohab_MixMat Mixing matrix on 'race'. Based on ego reports of the race / ethnicity / immigration status of their cohabiting partners, this matrix gives counts of ego-alter ties by the race of each individual for a hypothetical population. These counts are based on the NSFG mixing matrix. Only five categories of the 'race' variable are included here: Black, Black immigrant, Hispanic, Hispanic immigrant, and White.
cohab_PopWts Data frame of demographic characteristics together with relative counts (weights) in a hypothetical population. Individuals are classified according to five variables: age in years, race (same five categories of race / ethnicity / immigration status as above), sex (Male or Female), sexual identity (Female, Male who has sex with Females, or Male who has sex with Males or Females), and number of model-predicted persistent partnerships with noncohabiting partners ( 0 or 1 , where 1 means any nonzero value; the number is capped at 3 ), and number of partners ( 0 or 1 ).
cohab_TargetStats Vector of target (expected) statistics for a 15-term ERGM applied to a network of 50,000 nodes in which a tie represents a cohabitation relationship between two nodes. It is assumed for the purposes of these statistics that only male-female cohabitation relationships are allowed and that no individual may have such a relationship with more than one person. That is, each node must have degree zero or one. The ergm formula is: ~ edges + nodefactor("sex.ident", levels = 3) + nodecov("age") + nodecov("agesq") + nodefactor("race", levels = -5) + nodefactor("othr.net.deg", levels = -1) + nodematch("race", diff = TRUE) + absdiff("sqrt.age.adj")

ergm

```
coincidence-ergmTerm Coincident node count for the second mode in a bipartite (aka two-
                    mode) network
```

## Description

By default this term adds one network statistic to the model for each pair of nodes of mode two. It is equal to the number of (first mode) mutual partners of that pair. The first mode of a bipartite network object is sometimes known as the "actor" mode and the seconds as the "event" mode. So this is the number of actors going to both events in the pair. This term can only be used with undirected bipartite networks.

## Usage

\# binary: coincidence(levels=NULL,active=0)

## Arguments

levels specifies which pairs of nodes in mode two to include. (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)
active selects pairs for which the observed count is at least active. Ignored if levels is specified. (Thus, indices passed as levels should correspond to indices when levels $=$ NULL and active $=0$.)

## Note

ergm versions 3.9.4 and earlier used different arguments for this term. See ergm-options for how to invoke the old behaviour.

## See Also

ergmTerm for index of model terms currently visible to the package.
concurrent-ergmTerm Concurrent node count

## Description

This term adds one network statistic to the model, equal to the number of nodes in the network with degree 2 or higher. This term can only be used with undirected networks.

## Usage

\# binary: concurrent(by=NULL, levels=NULL)

## Arguments

by this optional argument specifies a vertex attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.) It functions just like the by argument of the degree term.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
concurrentties-ergmTerm
```

Concurrent tie count

## Description

This term adds one network statistic to the model, equal to the number of ties incident on each actor beyond the first. This term can only be used with undirected networks.

## Usage

\# binary: concurrentties(by=NULL, levels=NULL)

## Arguments

by
a vertex attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.); it functions just like the by argument of the degree term
levels TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)

## Arguments

drop Logical: If TRUE, terms whose observed statistic values are at the extremes of their possible ranges are dropped from the fit and their corresponding parameter estimates are set to plus or minus infinity, as appropriate. This is done because maximum likelihood estimates cannot exist when the vector of observed statistic lies on the boundary of the convex hull of possible statistic values.
init numeric or NA vector equal in length to the number of parameters in the model or NULL (the default); the initial values for the estimation and coefficient offset terms. If NULL is passed, all of the initial values are computed using the method specified by control\$init.method. If a numeric vector is given, the elements of the vector are interpreted as follows:

- Elements corresponding to terms enclosed in offset () are used as the fixed offset coefficients. Note that offset coefficients alone can be more conveniently specified using ergm() argument offset. coef. If both offset. coef and init arguments are given, values in offset. coef will take precedence.
- Elements that do not correspond to offset terms and are not NA are used as starting values in the estimation.
- Initial values for the elements that are NA are fit using the method specified by control\$init.method.
Passing control.ergm(init=coef(prev.fit)) can be used to "resume" an uncoverged ergm() run, though checkpoint and 'resume' would be better under most circumstances.
init.method A chatacter vector or NULL. The default method depends on the reference measure used. For the binary ("Bernoulli") ERGMs, with dyad-independent constraints, it's maximum pseudo-likelihood estimation (MPLE). Other valid values include "zeros" for a 0 vector of appropriate length and "CD" for contrastive divergence. If passed explicitly, this setting overrides the reference's limitations.
Valid initial methods for a given reference are set by the InitErgmReference.* function.
main.method One of "MCMLE" (default),"Robbins-Monro", "Stochastic-Approximation", or "Stepping". Chooses the estimation method used to find the MLE. MCMLE attempts to maximize an approximation to the log-likelihood function. Robbins-Monro and Stochastic-Approximation are both stochastic approximation algorithms that try to solve the method of moments equation that yields the MLE in the case of an exponential family model. Another alternative is a partial stepping algorithm (Stepping) as in Hummel et al. (2012). The direct use of the likelihood function has many theoretical advantages over stochastic approximation, but the choice will depend on the model and data being fit. See Handcock (2000) and Hunter and Handcock (2006) for details.
Note that in recent versions of ERGM, the enhancements of Stepping have been folded into the default MCMLE, which is able to handle more modeling scenarios; and Stepping may be removed in a future version.
force.main Logical: If TRUE, then force MCMC-based estimation method, even if the exact MLE can be computed via maximum pseudolikelihood estimation.
main.hessian Logical: If TRUE, then an approximate Hessian matrix is used in the MCMCbased estimation method.
checkpoint At the start of every iteration, save the state of the optimizer in a way that will allow it to be resumed. The name is passed through sprintf() with iteration number as the second argument. (For example, checkpoint="step_\%03d.RData" will save to step_001.RData, step_002.RData, etc.)
resume If given a file name of an RData file produced by checkpoint, the optimizer will attempt to resume after restoring the state. Control parameters from the saved state will be reused, except for those whose value passed via control.ergm() had change from the saved run. Note that if the network, the model, or some critical settings differ between runs, the results may be undefined.
MPLE.samplesize, init.MPLE.samplesize
These parameters control the maximum number of dyads (potential ties) that will be used by the MPLE to construct the predictor matrix for its logistic regression. In general, the algorithm visits dyads in a systematic sample that, if it does not hit one of these limits, will visit every informative dyad. If a limit is exceeded, case-control approximation to the likelihood, comprising all edges and those non-edges that have been visited by the algorithm before the limit was exceeded will be used.

MPLE. samplesize limits the number of dyads visited, unless the MPLE is being computed for the purpose of being the initial value for MCMC-based estimation, in which case init.MPLE. samplesize is used instead, All of these can be specified either as numbers or as function( $d, e$ ) taking the number of informative dyads and informative edges. Specifying or returning a larger number than the number of informative dyads is safe.
MPLE.type One of "glm", "penalized", or "logitreg". Chooses method of calculating MPLE. "glm" is the usual formal logistic regression called via glm, whereas "penalized" uses the bias-reduced method of Firth (1993) as originally implemented by Meinhard Ploner, Daniela Dunkler, Harry Southworth, and Georg Heinze in the "logistf" package. "logitreg" is an "in-house" implementation that is slower and probably less stable but supports nonlinear logistic regression. It is invoked automatically when the model has curved terms.
MPLE.maxit Maximum number of iterations for "logitreg" implementation of MPLE.
MPLE.nonident, MPLE.nonident.tol, MPLE.nonvar, MCMLE.nonident, MCMLE.nonident.tol, MCMLE.nonvar A rudimentary nonidentifiability/multicollinearity diagnostic. If MPLE . nonident. tol $>0$, test the MPLE covariate matrix or the CD statistics matrix has linearly dependent columns via QR decomposition with tolerance MPLE.nonident.tol. This is often (not always) indicative of a non-identifiable (multicollinear) model. If nonidentifiable, depending on MPLE . nonident issue a warning, an error, or a message specifying the potentially redundant statistics. Before the diagnostic is performed, covariates that do not vary (i.e., all-zero columns) are dropped, with their handling controlled by MPLE.nonvar. The corresponding MCMLE.* arguments provide a similar diagnostic for the unconstrained MCMC sample's estimating functions.
MPLE.constraints.ignore
If TRUE, MPLE will ignore all dyad-independent constraints except for those due to attributes missingness. This can be used to avert evaluating and storing the rlebdms for very large networks except where absolutely necessary. Note that this can be very dangerous unless you know what you are doing.
MCMC.prop Specifies the proposal (directly) and/or a series of "hints" about the structure of the model being sampled. The specification is in the form of a one-sided formula with hints separated by + operations. If the LHS exists and is a string, the proposal to be used is selected directly.
A common and default "hint" is $\sim$ sparse, indicating that the network is sparse and that the sample should put roughly equal weight on selecting a dyad with or without a tie as a candidate for toggling.
MCMC. prop.weights
Specifies the proposal distribution used in the MCMC Metropolis-Hastings algorithm. Possible choices depending on selected reference and constraints arguments of the ergm () function, but often include "TNT" and "random", and the "default" is to use the one with the highest priority available.
MCMC. prop.args An alternative, direct way of specifying additional arguments to proposal.
MCMC.interval Number of proposals between sampled statistics. Increasing interval will reduces the autocorrelation in the sample, and may increase the precision in estimates by reducing MCMC error, at the expense of time. Set the interval higher for larger networks.

MCMC.burnin Number of proposals before any MCMC sampling is done. It typically is set to a fairly large number.
MCMC.samplesize
Number of network statistics, randomly drawn from a given distribution on the set of all networks, returned by the Metropolis-Hastings algorithm. Increasing sample size may increase the precision in the estimates by reducing MCMC error, at the expense of time. Set it higher for larger networks, or when using parallel functionality.
MCMC.effectiveSize, MCMC.effectiveSize.damp, MCMC.effectiveSize.maxruns, MCMC.effectiveSize.burnin. p
Set MCMC.effectiveSize to a non-NULL value to adaptively determine the burn-in and the MCMC length needed to get the specified effective size; 50 is a reasonable value. In the adaptive MCMC mode, MCMC is run forward repeatedly (MCMC. samplesize*MCMC. interval steps, up to MCMC. effectiveSize.maxruns times) until the target effective sample size is reached or exceeded.
After each run, the returned statistics are mapped to the estimating function scale, then an exponential decay model is fit to the scaled statistics to find that burn-in which would reduce the difference between the initial values of statistics and their equilibrium values by a factor of MCMC. effectiveSize.burnin.scl of what it initially was, bounded by MCMC. effectiveSize.min and MCMC.effectiveSize. max as proportions of sample size. If the best-fitting decay exceeds MCMC. effectiveSize.max, the exponential model is considered to be unsuitable and MCMC. effectiveSize.min is used.
A Geweke diagnostic is then run, after thinning the sample to MCMC.effectiveSize.burnin. nmax. If this Geweke diagnostic produces a $p$-value higher than MCMC. effectiveSize.burnin. pval, it is accepted.
If MCMC.effectiveSize.burnin. PC>0, instead of using the full sample for burn-in estimation, at most this many principal components are used instead.
The effective size of the post-burn-in sample is computed via Vats, Flegal, and Jones (2015), and compared to the target effective size. If it is not matched, the MCMC run is resumed, with the additional draws needed linearly extrapolated but weighted in favor of the baseline MCMC. samplesize by the weighting factor MCMC. effectiveSize. damp (higher = less damping). Lastly, if after an MCMC run, the number of samples equals or exceeds $2 *$ MCMC. samplesize, the chain will be thinned by 2 until it falls below that, while doubling MCMC.interval. MCMC. effectiveSize. order.max can be used to set the order of the AR model used to estimate the effective sample size and the variance for the Geweke diagnostic.
MCMC.return.stats
Logical: If TRUE, return the matrix of MCMC-sampled network statistics. This matrix should have MCMC. samplesize rows. This matrix can be used directly by the coda package to assess MCMC convergence.
MCMC. runtime.traceplot
Logical: If TRUE, plot traceplots of the MCMC sample after every MCMC MLE iteration.
MCMC.maxedges The maximum number of edges that may occur during the MCMC sampling. If this number is exceeded at any time, sampling is stopped immediately.
MCMC.addto.se Whether to add the standard errors induced by the MCMC algorithm to the estimates' standard errors.

MCMC. packagenames
Names of packages in which to look for change statistic functions in addition to those autodetected. This argument should not be needed outside of very strange setups.

SAN.maxit When target.stats argument is passed to ergm(), the maximum number of attempts to use san to obtain a network with statistics close to those specified.
SAN.nsteps.times
Multiplier for SAN.nsteps relative to MCMC. burnin. This lets one control the amount of SAN burn-in (arguably, the most important of SAN parameters) without overriding the other SAN defaults.

SAN Control arguments to san. See control.san for details.
MCMLE. termination
The criterion used for terminating MCMLE estimation:

- "Hummel" Terminate when the Hummel step length is 1 for two consecutive iterations. For the last iteration, the sample size is boosted by a factor of MCMLE. last. boost. See Hummel et. al. (2012).

Note that this criterion is incompatible with MCMLE.steplength $\neq 1$ or MCMLE. steplength.margin $=$ NULL.

- "Hotelling" After every MCMC sample, an autocorrelation-adjusted Hotelling's $\mathrm{T}^{\wedge} 2$ test for equality of MCMC-simulated network statistics to observed is conducted, and if its P-value exceeds MCMLE.conv.min.pval, the estimation is considered to have converged and finishes. This was the default option in ergm version 3.1.
- "precision" Terminate when the estimated loss in estimating precision due to using MCMC standard errors is below the precision bound specified by MCMLE.MCMC.precision, and the Hummel step length is 1 for two consecutive iterations. See MCMLE.MCMC.precision for details. This feature is in experimental status until we verify the coverage of the standard errors.
Note that this criterion is incompatible with MCMLE.steplength $\neq 1$ or MCMLE.steplength.margin $=$ NULL.
- "confidence": Performs an equivalence test to prove with level of confidence MCMLE. confidence that the true value of the deviation of the simulated mean value parameter from the observed is within an ellipsoid defined by the inverse-variance-covariance of the sufficient statistics multiplied by a scaling factor control\$MCMLE.MCMC.precision (which has a different default).
- "none" Stop after MCMLE . maxit iterations.

MCMLE.maxit Maximum number of times the parameter for the MCMC should be updated by maximizing the MCMC likelihood. At each step the parameter is changed to the values that maximizes the MCMC likelihood based on the current sample.
MCMLE.conv.min.pval
The P-value used in the Hotelling test for early termination.
MCMLE.confidence
The confidence level for declaring convergence for "confidence" methods.

## MCMLE.confidence.boost

The maximum increase factor in sample size (or target effective size, if enabled) when the "confidence" termination criterion is either not approaching the tolerance region or is unable to prove convergence.
MCMLE.confidence.boost. threshold, MCMLE.confidence.boost.lag
Sample size or target effective size will be increaed if the distance from the tolerance region fails to decrease more than MCMLE.confidence.boost.threshold in this many successive iterations.
MCMLE.NR.maxit, MCMLE.NR.reltol
The method, maximum number of iterations and relative tolerance to use within the optim rountine in the MLE optimization. Note that by default, ergm uses trust, and falls back to optim only when trust fails.
obs.MCMC.prop, obs.MCMC.prop.weights, obs.MCMC.prop.args, obs.MCMLE.effectiveSize, obs.MCMC.samplesiz
Corresponding MCMC parameters and settings used for the constrained sample when unobserved data are present in the estimation routine. By default, they are controlled by the *.mul parameters, as fractions of the corresponding settings for the unconstrained (standard) MCMC.
These can, in turn, be controlled by obs.MCMC.mul, which can be used to set the overal multiplier for the number of MCMC steps in the constrained sample; one half of its effect applies to the burn-in and interval and the other half to the total sample size. For example, for obs.MCMC.mul=1/4 (the default), obs.MCMC. samplesize is set to $\sqrt{1 / 4}=1 / 2$ that of obs.MCMC. samplesize, and obs.MCMC. burnin and obs.MCMC. interval are set to $\sqrt{1 / 4}=1 / 2$ of their respective unconstrained sampling parameters. When MCMC.effectiveSize or MCMLE. effectiveSize are given, their corresponding obs parameters are set to them multiplied by obs.MCMC.mul.
obs.MCMC.impute.min_informative, obs.MCMC.impute.default_density
Controls for imputation of missing dyads for initializing MCMC sampling. If numeric, obs.MCMC.impute.min_informative specifies the minimum number dyads that need to be non-missing before sample network density is used as the imputation density. It can also be specified as a function that returns this value. obs.MCMC.impute.default_density similarly controls the imputation density when number of non-missing dyads is too low.
MCMLE.min.depfac, MCMLE.sampsize.boost. pow
When using adaptive MCMC effective size, and methods that increase the MCMC sample size, use MCMLE. sampsize. boost. pow as the power of the boost amount (relative to the boost of the target effective size), but ensure that sample size is no less than MCMLE. min. depfac times the target effective size.
MCMLE.MCMC.precision, MCMLE.MCMC.max.ESS.frac
MCMLE.MCMC. precision is a vector of upper bounds on the standard errors induced by the MCMC algorithm, expressed as a percentage of the total standard error. The MCMLE algorithm will terminate when the MCMC standard errors are below the precision bound, and the Hummel step length is 1 for two consecutive iterations. This is an experimental feature.
If effective sample size is used (see MCMC. effectiveSize), then ergm may increase the target ESS to reduce the MCMC standard error.
MCMLE.metric Method to calculate the loglikelihood approximation. See Hummel et al (2010) for an explanation of "lognormal" and "naive".

MCMLE.method Deprecated. By default, ergm uses trust, and falls back to optim with NelderMead method when trust fails.
MCMLE.dampening
(logical) Should likelihood dampening be used?
MCMLE.dampening.min.ess
The effective sample size below which dampening is used.

## MCMLE. dampening.level

The proportional distance from boundary of the convex hull move.
MCMLE. steplength.margin
The extra margin required for a Hummel step to count as being inside the convex hull of the sample. Set this to 0 if the step length gets stuck at the same value over several iteraions. Set it to NULL to use fixed step length. Note that this parameter is required to be non-NULL for MCMLE termination using Hummel or precision criteria.
MCMLE.steplength
Multiplier for step length (on the mean-value parameter scale), which may (for values less than one) make fitting more stable at the cost of computational efficiency.
If MCMLE. steplength.margin is not NULL, the step length will be set using the algorithm of Hummel et al. (2010). In that case, it will serve as the maximum step length considered. However, setting it to anything other than 1 will preclude using Hummel or precision as termination criteria.
MCMLE.steplength. parallel
Whether parallel multisection search (as opposed to a bisection search) for the Hummel step length should be used if running in multiple threads. Possible values (partially matched) are "never", and (default) "observational" (i.e., when missing data MLE is used).
MCMLE.sequential
Logical: If TRUE, the next iteration of the fit uses the last network sampled as the starting network. If FALSE, always use the initially passed network. The results should be similar (stochastically), but the TRUE option may help if the target. stats in the ergm() function are far from the initial network.
MCMLE.density.guard.min, MCMLE.density.guard
A simple heuristic to stop optimization if it finds itself in an overly dense region, which usually indicates ERGM degeneracy: if the sampler encounters a network configuration that has more than MCMLE.density.guard.min edges and whose number of edges is exceeds the observed network by more than MCMLE. density.guard, the optimization process will be stopped with an error.
MCMLE.effectiveSize, MCMLE.effectiveSize.interval_drop, MCMLE.burnin, MCMLE.interval, MCMLE.samplesiz
Sets the corresponding MCMC.* parameters when main.method="MCMLE" (the default). Used because defaults may be different for different methods. MCMLE. samplesize.per_theta controls the MCMC sample size (not target effective size) as a function of the number of (curved) parameters in the model, and MCMLE. samplesize.min sets the minimum sample size regardless of their number.
MCMLE.steplength.solver
The linear program solver to use for MCMLE step length calculation. Can be either "glpk" to use Rglpk or "lpsolve" to use lpSolveAPI. Rglpk can be
orders of magnitude faster, particularly for models with many parameters and with large sample sizes, so it is used where available; but it requires an external library to install under some operating systems, so fallback to lpSolveAPI provided.
MCMLE.last.boost
For the Hummel termination criterion, increase the MCMC sample size of the last iteration by this factor.
MCMLE.steplength.esteq
For curved ERGMs, should the estimating function values be used to compute the Hummel step length? This allows the Hummel stepping algorithm converge when some sufficient statistics are at 0 .
MCMLE.steplength.miss.sample
In fitting the missing data MLE, the rules for step length become more complicated. In short, it is necessary for all points in the constrained sample to be in the convex hull of the unconstrained (though they may be on the border); and it is necessary for their centroid to be in its interior. This requires checking a large number of points against whether they are in the convex hull, so to speed up the procedure, a sample is taken of the points most likely to be outside it. This parameter specifies the sample size or a function of the unconstrained sample matrix to determine the sample size.
MCMLE.steplength.min
Stops MCMLE estimation when the step length gets stuck below this minimum value.
MCMLE.save_intermediates
Every iteration, after MCMC sampling, save the MCMC sample and some miscellaneous information to a file with this name. This is mainly useful for diagnostics and debugging. The name is passed through sprintf() with iteration number as the second argument. (For example, MCMLE. save_intermediates="step_\%03d.RData" will save to step_001.RData, step_002.RData, etc.)
SA. phase1_n Number of MCMC samples to draw in Phase 1 of the stochastic approximation algorithm. Defaults to 7 plus 3 times the number of terms in the model. See Snijders (2002) for details.
SA.initial_gain
Initial gain to Phase 2 of the stochastic approximation algorithm. See Snijders (2002) for details.

SA.nsubphases Number of sub-phases in Phase 2 of the stochastic approximation algorithm. Defaults to MCMLE . maxit. See Snijders (2002) for details.
SA.niterations Number of MCMC samples to draw in Phase 2 of the stochastic approximation algorithm. Defaults to 7 plus the number of terms in the model. See Snijders (2002) for details.

SA.phase3_n Sample size for the MCMC sample in Phase 3 of the stochastic approximation algorithm. See Snijders (2002) for details.
SA.burnin, SA.interval, SA. samplesize
Sets the corresponding MCMC. * parameters when main.method="Stochastic-Approximation".
RM.phase1n_base, RM.phase2n_base, RM.phase2sub, RM.init_gain, RM. phase3n
The Robbins-Monro control parameters are not yet documented.

| RM. burnin, RM.interval, RM. samplesize |  |
| :---: | :---: |
|  | Sets the corresponding MCMC . * parameters when main.method="Robbins-Monro". |
| Step.maxit | Maximum number of iterations (steps) allowed by the "Stepping" method. |
| Step.gridsize | Integer $N$ such that the "Stepping" style of optimization chooses a step length equal to the largest possible multiple of $1 / N$. See Hummel et al. (2012) for details. |
| Step.burnin, Step.interval, Step. samplesize |  |
| Sets the corresponding MCMC.* parameters when main.method="Stepping". |  |
| CD.samplesize.per_theta, obs.CD.samplesize.per_theta, CD.maxit, CD.conv.min.pval, CD |  |
|  | Miscellaneous tuning parameters of the CD sampler and optimizer. These have the same meaning as their MCMLE. * and MCMC. * counterparts. |
|  | Note that only the Hotelling's stopping criterion is implemented for CD. |
| CD.nsteps, CD.multiplicity |  |
|  | Main settings for contrastive divergence to obtain initial values for the estimation: respectively, the number of Metropolis-Hastings steps to take before reverting to the starting value and the number of tentative proposals per step. Computational experiments indicate that increasing CD.multiplicity improves the estimate faster than increasing CD. nsteps - up to a point - but it also samples from the wrong distribution, in the sense that while as CD.nsteps $\rightarrow \infty$, the CD estimate approaches the MLE, this is not the case for CD.multiplicity. |
|  | In practice, MPLE, when available, usually outperforms CD for even a very high CD.nsteps (which is, in turn, not very stable), so CD is useful primarily when MPLE is not available. This feature is to be considered experimental and in flux. |
|  | The default values have been set experimentally, providing a reasonably stable, if not great, starting values. |
| CD.nsteps.obs, CD.multiplicity.obs |  |
|  | When there are missing dyads, CD.nsteps and CD.multiplicity must be set to a relatively high value, as the network passed is not necessarily a good start for CD. Therefore, these settings are in effect if there are missing dyads in the observed network, using a higher default number of steps. |
| loglik | See control.ergm. bridge |
| term.options | A list of additional arguments to be passed to term initializers. See ? term. options. |
| seed | Seed value (integer) for the random number generator. See set. seed |
| parallel | Number of threads in which to run the sampling. Defaults to 0 (no parallelism). See the entry on parallel processing for details and troubleshooting. |
| parallel.type | API to use for parallel processing. Supported values are "MPI" and "PSOCK". Defaults to using the parallel package with PSOCK clusters. See ergm-parallel |
| parallel.version.check |  |
|  | Logical: If TRUE, check that the version of ergm running on the slave nodes is the same as that running on the master node. |
| parallel.inherit.MT |  |
|  | Logical: If TRUE, slave nodes and processes inherit the set.MT_terms() setting. |
|  | A dummy argument to catch deprecated or mistyped control parameters. |

## Details

This function is only used within a call to the ergm() function. See the usage section in ergm() for details.

## Value

A list with arguments as components.

ergm(). The control.simulate function performs a similar function for simulate.ergm; control.gof performs a similar function for gof.

```
control.ergm.bridge Auxiliaries for Controlling ergm.bridge.llr() and logLik.ergm()
```

## Description

Auxiliary functions as user interfaces for fine-tuning the ergm.bridge.llr() algorithm, which approximates log likelihood ratios using bridge sampling.
By default, the bridge sampler inherits its control parameters from the ergm() fit; control.logLik.ergm() allows the user to selectively override them.

## Usage

control.ergm.bridge(
bridge.nsteps = 16,
bridge.target.se = NULL,
bridge.bidirectional = TRUE,
MCMC.burnin = MCMC.interval * 128,
MCMC. burnin.between $=\max ($ ceiling (MCMC.burnin/sqrt(bridge. nsteps)) , MCMC. interval *
16),

MCMC.interval = 128,
MCMC. samplesize $=16384$,
obs.MCMC.burnin $=$ obs.MCMC.interval * 128,
obs.MCMC.burnin.between $=\max (c e i l i n g(o b s . M C M C . b u r n i n / s q r t(b r i d g e . n s t e p s))$, obs.MCMC.interval * 16),
obs.MCMC.interval = MCMC.interval,
obs.MCMC.samplesize = MCMC. samplesize,
MCMC.prop $=$ trim_env(~sparse),
MCMC.prop.weights = "default",
MCMC. prop.args = list(),
obs.MCMC.prop = MCMC. prop,
obs.MCMC.prop.weights = MCMC.prop.weights,
obs.MCMC.prop.args = MCMC.prop.args,
MCMC.maxedges = Inf,
MCMC. packagenames $=c()$,
term.options = list(),
seed $=$ NULL,
parallel = 0,
parallel.type $=$ NULL,
parallel.version.check = TRUE,
parallel.inherit.MT = FALSE,
)
control.logLik.ergm(
bridge.nsteps = 16,
bridge.target.se $=$ NULL,
bridge.bidirectional = TRUE,
MCMC. burnin = NULL,

    )
```

## Arguments

bridge.nsteps Number of geometric bridges to use.
bridge.target.se
If not NULL, if the estimated MCMC standard error of the likelihood estimate exceeds this, repeat the bridge sampling, accumulating samples.
bridge.bidirectional
Whether the bridge sampler first bridges from from to to, then from to to from (skipping the first burn-in), etc. if multiple attempts are required.
MCMC.burnin Number of proposals before any MCMC sampling is done. It typically is set to a fairly large number.
MCMC.burnin.between
Number of proposals between the bridges; typically, less and less is needed as the number of steps decreases.
MCMC. interval Number of proposals between sampled statistics.
MCMC. samplesize
Number of network statistics, randomly drawn from a given distribution on the set of all networks, returned by the Metropolis-Hastings algorithm.
obs.MCMC.burnin, obs.MCMC.burnin.between, obs.MCMC.interval, obs.MCMC. samplesize
The obs versions of these arguments are for the unobserved data simulation algorithm.

MCMC.prop Specifies the proposal (directly) and/or a series of "hints" about the structure of the model being sampled. The specification is in the form of a one-sided formula with hints separated by + operations. If the LHS exists and is a string, the proposal to be used is selected directly.
A common and default "hint" is $\sim$ sparse, indicating that the network is sparse and that the sample should put roughly equal weight on selecting a dyad with or without a tie as a candidate for toggling.
MCMC. prop.weights
Specifies the proposal distribution used in the MCMC Metropolis-Hastings algorithm. Possible choices depending on selected reference and constraints arguments of the ergm () function, but often include "TNT" and "random", and the "default" is to use the one with the highest priority available.
MCMC. prop.args An alternative, direct way of specifying additional arguments to proposal.
obs.MCMC.prop, obs.MCMC.prop.weights, obs.MCMC.prop.args
The obs versions of these arguments are for the unobserved data simulation algorithm.
MCMC.maxedges The maximum number of edges that may occur during the MCMC sampling. If this number is exceeded at any time, sampling is stopped immediately.
MCMC. packagenames
Names of packages in which to look for change statistic functions in addition to those autodetected. This argument should not be needed outside of very strange setups.

```
term.options A list of additional arguments to be passed to term initializers. See ? term.options.
seed Seed value (integer) for the random number generator. See set.seed.
parallel Number of threads in which to run the sampling. Defaults to 0 (no parallelism).
    See the entry on parallel processing for details and troubleshooting.
parallel.type API to use for parallel processing. Supported values are "MPI" and "PSOCK".
    Defaults to using the parallel package with PSOCK clusters. See ergm-parallel
parallel.version.check
    Logical: If TRUE, check that the version of ergm running on the slave nodes is
    the same as that running on the master node.
parallel.inherit.MT
    Logical: If TRUE, slave nodes and processes inherit the set.MT_terms() set-
    ting.
.. . A dummy argument to catch deprecated or mistyped control parameters.
```

## Details

control.ergm.bridge() is only used within a call to the ergm.bridge.llr(), ergm.bridge.dindstart.llk(), or ergm.bridge.0.llk() functions.
control. logLik.ergm() is only used within a call to the logLik.ergm().

## Value

A list with arguments as components.

## See Also

```
ergm.bridge.llr()
```

logLik.ergm

```
control.ergm.godfather
```

    Control parameters for ergm. godfather().
    
## Description

Returns a list of its arguments.

## Usage

control.ergm.godfather(term.options = NULL)

## Arguments

term.options A list of additional arguments to be passed to term initializers. See ? term. options.

## Description

Auxiliary function as user interface for fine-tuning ERGM Goodness-of-Fit Evaluation.
The control.gof.ergm version is intended to be used with gof.ergm() specifically and will "inherit" as many control parameters from ergm fit as possible().

## Usage

control.gof.formula(
nsim $=100$,
MCMC. burnin $=10000$,
MCMC. interval $=1000$,
MCMC. batch $=0$,
MCMC. prop $=$ trim_env(~sparse),
MCMC.prop.weights = "default",
MCMC. prop.args = list(),
MCMC. maxedges = Inf,
MCMC. packagenames $=c()$,
MCMC. runtime.traceplot = FALSE, network.output = "network", seed $=$ NULL, parallel $=0$, parallel.type $=$ NULL, parallel.version.check = TRUE, parallel.inherit.MT = FALSE
)
control.gof.ergm(
nsim = 100,
MCMC. burnin = NULL,
MCMC. interval $=$ NULL,
MCMC. batch $=$ NULL,
MCMC. prop $=$ NULL,
MCMC. prop.weights $=$ NULL,
MCMC. prop.args $=$ NULL,
MCMC. maxedges $=$ NULL,
MCMC. packagenames $=$ NULL,
MCMC. runtime.traceplot = FALSE,
network.output = "network",
seed $=$ NULL,
parallel = 0,
parallel.type $=$ NULL,
parallel.version.check = TRUE,

```
    parallel.inherit.MT = FALSE
)
```

## Arguments

nsim Number of networks to be randomly drawn using Markov chain Monte Carlo. This sample of networks provides the basis for comparing the model to the observed network.
MCMC. burnin Number of proposals before any MCMC sampling is done. It typically is set to a fairly large number.
MCMC. interval Number of proposals between sampled statistics.
MCMC.batch if not 0 or NULL, sample about this many networks per call to the lower-level code; this can be useful if output= is a function, where it can be used to limit the number of networks held in memory at any given time.
MCMC.prop Specifies the proposal (directly) and/or a series of "hints" about the structure of the model being sampled. The specification is in the form of a one-sided formula with hints separated by + operations. If the LHS exists and is a string, the proposal to be used is selected directly.
A common and default "hint" is $\sim$ sparse, indicating that the network is sparse and that the sample should put roughly equal weight on selecting a dyad with or without a tie as a candidate for toggling.
MCMC. prop.weights
Specifies the proposal distribution used in the MCMC Metropolis-Hastings algorithm. Possible choices depending on selected reference and constraints arguments of the ergm () function, but often include "TNT" and "random", and the "default" is to use the one with the highest priority available.
MCMC. prop.args An alternative, direct way of specifying additional arguments to proposal.
MCMC.maxedges The maximum number of edges that may occur during the MCMC sampling. If this number is exceeded at any time, sampling is stopped immediately.
MCMC. packagenames
Names of packages in which to look for change statistic functions in addition to those autodetected. This argument should not be needed outside of very strange setups.
MCMC. runtime.traceplot
Logical: If TRUE, plot traceplots of the MCMC sample.
network. output R class with which to output networks. The options are "network" (default) and "edgelist.compressed" (which saves space but only supports networks without vertex attributes)
seed Seed value (integer) for the random number generator. See set. seed.
parallel Number of threads in which to run the sampling. Defaults to 0 (no parallelism). See the entry on parallel processing for details and troubleshooting.
parallel.type API to use for parallel processing. Supported values are "MPI" and "PSOCK". Defaults to using the parallel package with PSOCK clusters. See ergm-parallel
parallel.version.check
Logical: If TRUE, check that the version of ergm running on the slave nodes is the same as that running on the master node.
parallel.inherit.MT
Logical: If TRUE, slave nodes and processes inherit the set.MT_terms() setting.

## Details

This function is only used within a call to the gof function. See the usage section in gof for details.

## Value

A list with arguments as components.

## See Also

gof. The control.simulate function performs a similar function for simulate.ergm; control.ergm performs a similar function for ergm.

```
control.san Auxiliary for Controlling SAN
```

## Description

Auxiliary function as user interface for fine-tuning simulated annealing algorithm.

## Usage

control.san(
SAN.maxit $=4$, SAN. tau = 1, SAN.invcov = NULL, SAN.invcov.diag = FALSE, SAN.nsteps.alloc = function(nsim) 2^seq_len(nsim), SAN.nsteps = 2^19, SAN. samplesize $=2^{\wedge} 12$, SAN. prop = trim_env(~sparse), SAN.prop.weights = "default", SAN.prop.args = list(), SAN. packagenames $=c()$, SAN.ignore.finite.offsets = TRUE, term.options = list(), seed $=$ NULL, parallel = 0, parallel.type = NULL, parallel.version.check = TRUE, parallel.inherit.MT = FALSE
)

## Arguments

SAN.maxit Number of temperature levels to use.
SAN.tau Tuning parameter, specifying the temperature of the process during the penultimate iteration. (During the last iteration, the temperature is set to 0 , resulting in a greedy search, and during the previous iterations, the temperature is set to SAN.tau*(iterations left after this one).

SAN.invcov Initial inverse covariance matrix used to calculate Mahalanobis distance in determining how far a proposed MCMC move is from the target. stats vector. If NULL, initially set to the identity matrix. In either case, during subsequent runs, it is estimated empirically.
SAN.invcov.diag
Whether to only use the diagonal of the covariance matrix. It seems to work better in practice.
SAN.nsteps.alloc
Either a numeric vector or a function of the number of runs giving a sequence of relative lengths of simulated annealing runs.

SAN.nsteps Number of MCMC proposals for all the annealing runs combined.
SAN. samplesize Number of realisations' statistics to obtain for tuning purposes.
SAN.prop Specifies the proposal (directly) and/or a series of "hints" about the structure of the model being sampled. The specification is in the form of a one-sided formula with hints separated by + operations. If the LHS exists and is a string, the proposal to be used is selected directly.
A common and default "hint" is $\sim$ sparse, indicating that the network is sparse and that the sample should put roughly equal weight on selecting a dyad with or without a tie as a candidate for toggling.
SAN.prop.weights
Specifies the proposal distribution used in the SAN Metropolis-Hastings algorithm. Possible choices depending on selected reference and constraints arguments of the ergm() function, but often include "TNT" and "random", and the "default" is to use the one with the highest priority available.

SAN.prop.args An alternative, direct way of specifying additional arguments to proposal.
SAN.packagenames
Names of packages in which to look for change statistic functions in addition to those autodetected. This argument should not be needed outside of very strange setups.
SAN.ignore.finite.offsets
Whether SAN should ignore (treat as 0 ) finite offsets.
term. options A list of additional arguments to be passed to term initializers. See ? term. options.
seed Seed value (integer) for the random number generator. See set. seed.
parallel Number of threads in which to run the sampling. Defaults to 0 (no parallelism). See the entry on parallel processing for details and troubleshooting.
parallel.type API to use for parallel processing. Supported values are "MPI" and "PSOCK". Defaults to using the parallel package with PSOCK clusters. See ergm-parallel
parallel.version.check
Logical: If TRUE, check that the version of ergm running on the slave nodes is the same as that running on the master node.
parallel.inherit.MT
Logical: If TRUE, slave nodes and processes inherit the set.MT_terms() setting.

## Details

This function is only used within a call to the san function. See the usage section in san for details.

## Value

A list with arguments as components.

## See Also

san

```
control.simulate.ergm Auxiliary for Controlling ERGM Simulation
```

## Description

Auxiliary function as user interface for fine-tuning ERGM simulation. control. simulate, control.simulate.formula, and control.simulate.formula.ergm are all aliases for the same function.
While the others supply a full set of simulation settings, control.simulate.ergm when passed as a control parameter to simulate. $\operatorname{ergm}()$ allows some settings to be inherited from the ERGM stimation while overriding others.

## Usage

control.simulate.formula.ergm(

    parallel.inherit.MT = FALSE,
    ...
)
```

## Arguments

MCMC.burnin Number of proposals before any MCMC sampling is done. It typically is set to a fairly large number.
MCMC. interval Number of proposals between sampled statistics.
MCMC.prop Specifies the proposal (directly) and/or a series of "hints" about the structure of the model being sampled. The specification is in the form of a one-sided formula with hints separated by + operations. If the LHS exists and is a string, the proposal to be used is selected directly.
A common and default "hint" is $\sim$ sparse, indicating that the network is sparse and that the sample should put roughly equal weight on selecting a dyad with or without a tie as a candidate for toggling.
MCMC. prop.weights
Specifies the proposal distribution used in the MCMC Metropolis-Hastings algorithm. Possible choices depending on selected reference and constraints arguments of the ergm () function, but often include "TNT" and "random", and the "default" is to use the one with the highest priority available.
MCMC. prop.args An alternative, direct way of specifying additional arguments to proposal.
MCMC.batch if not 0 or NULL, sample about this many networks per call to the lower-level code; this can be useful if output= is a function, where it can be used to limit the number of networks held in memory at any given time.
MCMC.effectiveSize, MCMC.effectiveSize.damp, MCMC.effectiveSize.maxruns, MCMC.effectiveSize.burnin. p Set MCMC.effectiveSize to a non-NULL value to adaptively determine the burn-in and the MCMC length needed to get the specified effective size; 50 is a reasonable value. In the adaptive MCMC mode, MCMC is run forward repeatedly (MCMC. samplesize*MCMC. interval steps, up to MCMC. effectiveSize.maxruns times) until the target effective sample size is reached or exceeded.
After each run, the returned statistics are mapped to the estimating function scale, then an exponential decay model is fit to the scaled statistics to find that burn-in which would reduce the difference between the initial values of statistics and their equilibrium values by a factor of MCMC.effectiveSize.burnin.scl of what it initially was, bounded by MCMC. effectiveSize.min and MCMC. effectiveSize. max as proportions of sample size. If the best-fitting decay exceeds MCMC. effectiveSize.max, the exponential model is considered to be unsuitable and MCMC. effectiveSize.min is used.
A Geweke diagnostic is then run, after thinning the sample to MCMC. effectiveSize.burnin. nmax. If this Geweke diagnostic produces a $p$-value higher than MCMC.effectiveSize.burnin. pval, it is accepted.

If MCMC.effectiveSize.burnin.PC>0, instead of using the full sample for burn-in estimation, at most this many principal components are used instead.
The effective size of the post-burn-in sample is computed via Vats, Flegal, and Jones (2015), and compared to the target effective size. If it is not matched, the MCMC run is resumed, with the additional draws needed linearly extrapolated but weighted in favor of the baseline MCMC. samplesize by the weighting factor MCMC. effectiveSize. damp (higher = less damping). Lastly, if after an MCMC run, the number of samples equals or exceeds $2 *$ MCMC. samplesize, the chain will be thinned by 2 until it falls below that, while doubling MCMC.interval. MCMC. effectiveSize. order.max can be used to set the order of the AR model used to estimate the effective sample size and the variance for the Geweke diagnostic.

MCMC.maxedges The maximum number of edges that may occur during the MCMC sampling. If this number is exceeded at any time, sampling is stopped immediately.
MCMC. packagenames
Names of packages in which to look for change statistic functions in addition to those autodetected. This argument should not be needed outside of very strange setups.
MCMC. runtime. traceplot
Logical: If TRUE, plot traceplots of the MCMC sample.
network. output R class with which to output networks. The options are "network" (default) and "edgelist.compressed" (which saves space but only supports networks without vertex attributes)
term. options A list of additional arguments to be passed to term initializers. See ? term. options.
parallel Number of threads in which to run the sampling. Defaults to 0 (no parallelism). See the entry on parallel processing for details and troubleshooting.
parallel.type API to use for parallel processing. Supported values are "MPI" and "PSOCK". Defaults to using the parallel package with PSOCK clusters. See ergm-parallel
parallel.version.check
Logical: If TRUE, check that the version of ergm running on the slave nodes is the same as that running on the master node.
parallel.inherit.MT
Logical: If TRUE, slave nodes and processes inherit the set.MT_terms() setting.
... A dummy argument to catch deprecated or mistyped control parameters.
MCMC.scale For control.simulate.ergm() inheriting MCMC.burnin and MCMC.interval from the ergm fit, the multiplier for the inherited values. This can be useful because MCMC parameters used in the fit are tuned to generate a specific effective sample size for the sufficient statistic in a large MCMC sample, so the inherited values might not generate independent realisations.

## Details

This function is only used within a call to the simulate function. See the usage section in simulate. ergm for details.

## Value

A list with arguments as components.

## See Also

simulate.ergm, simulate.formula. control.ergm performs a similar function for ergm; control.gof performs a similar function for gof.

```
ctriple-ergmTerm Cyclic triples
```

## Description

By default, this term adds one statistic to the model, equal to the number of cyclic triples in the network, defined as a set of edges of the form $\{(i \rightarrow j),(j \rightarrow k),(k \rightarrow i)\}$.

## Usage

\# binary: ctriple(attr=NULL, diff=FALSE, levels=NULL)
\# binary: ctriad

## Arguments

$\begin{array}{ll}\text { attr, diff } & \begin{array}{l}\text { quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) } \\ \text { for details.) If attr is specified and diff is FALSE, then the statistic is the num- } \\ \text { ber of cyclic triples where all three nodes have the same value of the attribute. If } \\ \text { attr is specified and diff is TRUE, then one statistic is added to the model for } \\ \text { each value of attr, equal to the number of cyclic triples where all three nodes } \\ \text { have that value of the attribute. }\end{array} \\ \text { levels } & \begin{array}{l}\text { specifies the value of attr to consider if attr is passed and diff=TRUE. (See } \\ \text { Specifying Vertex attributes and Levels (?nodal_attributes) for details.) }\end{array}\end{array}$

## Note

This term can only be used with directed networks.
for all directed networks, triangle is equal to ttriple+ctriple, so at most two of these three terms can be in a model.

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

Arguments may have the same forms as in the API, but for convenience, alternative forms are accepted.
If the model in formula is curved, then the outputs of this operator term's map argument will be used as inputs to the curved terms of the formula model.
Curve is an obsolete alias and may be deprecated and removed in a future release.

## Usage

\# binary: Curve(formula, params, map, gradient=NULL, minpar=-Inf, maxpar=+Inf, cov=NULL)
\# binary: Parametrise(formula, params, map, gradient=NULL, minpar=-Inf, maxpar=+Inf,
\# cov=NULL)
\# binary: Parametrize(formula, params, map, gradient=NULL, minpar=-Inf, maxpar=+Inf,
\# cov=NULL)
\# valued: Curve(formula, params, map, gradient=NULL, minpar=-Inf, maxpar=+Inf, cov=NULL)
\# valued: Parametrise(formula, params, map, gradient=NULL, minpar=-Inf, maxpar=+Inf, \# cov=NULL)
\# valued: Parametrize(formula, params, map, gradient=NULL, minpar=-Inf, maxpar=+Inf, \# cov=NULL)

## Arguments

formula a one-sided ergm()-style formula with the terms to be evaluated
params a named list whos names are the curved parameter names, may also be a character vector with names.
map the mapping from curved to canonical. May have the following forms:

- a function ( $x, n, \ldots$ ) treated as in the API: called with $x$ set to the curved parameter vector, $n$ to the length of output expected, and cov, if present, passed in . . . . The function must return a numeric vector of length n .
- a numeric vector to fix the output coefficients, like in an offset.
- a character string to select (partially-matched) one of predefined forms. Currently, the defined forms include:
- "rep" recycle the input vector to the length of the output vector as a rep function would.
gradient its gradient function. It is optional if map is constant or one of the predefined forms; otherwise it must have one of the following forms:
- a function ( $x, n, \ldots$ ) treated as in the API: called with $x$ set to the curved parameter vector, $n$ to the length of output expected, and cov, if present, passed in ... . The function must return a numeric matrix with length (params) rows and $n$ columns.
- a numeric matrix to fix the gradient; this is useful when map is linear.
- a character string to select (partially-matched) one of predefined forms. Currently, the defined forms include:
- "linear" calculate the (constant) gradient matrix using finite differences. Note that this will be done only once at the initialization stage, so use only if you are certain map is, in fact, linear.
minpar, maxpar the minimum and maximum allowed curved parameter values. The parameters will be recycled to the appropriate length.
cov optional

## See Also

ergmTerm for index of model terms currently visible to the package.

```
cycle-ergmTerm k-Cycle Census
```

## Description

This term adds one network statistic to the model for each value of $k$, corresponding to the number of k-cycles (or, alternately, semicycles) in the graph.
This term can be used with either directed or undirected networks.

## Usage

\# binary: cycle(k, semi=FALSE)

## Arguments

k
a vector of integers giving the cycle lengths to count. Directed cycle lengths may range from 2 to N (the network size); undirected cycle lengths and semicycle lengths may range from 3 to $N$; length 2 semicycles are not currently supported.
semi an optional logical indicating whether semicycles (rather than directed cycles) should be counted; this is ignored in the undirected case.
directed 2-cycles are equivalent to mutual dyads.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
cyclicalties-ergmTerm Cyclical ties
```

## Description

This term adds one statistic, equal to the number of ties $i \rightarrow j$ such that there exists a two-path from $j$ to $i$. (Related to the ttriple term.)

## Usage

\# binary: cyclicalties(attr=NULL, levels=NULL)
\# valued: cyclicalties(threshold=0)

## Arguments

attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.) If set, all three nodes involved ( $i, j$, and the node on the two-path) must match on this attribute in order for $i \rightarrow j$ to be counted.
levels TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)

## See Also

ergmTerm for index of model terms currently visible to the package.

```
cyclicalweights-ergmTerm
```

Cyclical weights

## Description

This statistic implements the cyclical weights statistic, like that defined by Krivitsky (2012), Equation 13, but with the focus dyad being $y_{j, i}$ rather than $y_{i, j}$. For each option, the first (and the default) is more stable but also more conservative, while the second is more sensitive but more likely to induce a multimodal distribution of networks.

## Usage

```
    # valued: cyclicalweights(twopath="min", combine="max", affect="min")
```

## Arguments

```
    twopath the minimum of the constituent dyads ( "min") or their geometric mean (
                        "geomean")
    combine the maximum of the 2-path strengths ("max") or their sum ("sum")
    affected the minimum of the focus dyad and the combined strength of the two paths (
        "min") or their geometric mean ("geomean")
```

## See Also

ergmTerm for index of model terms currently visible to the package.
ddsp-ergmTerm Directed dyadwise shared partners

## Description

This term adds one network statistic to the model for each element in d where the $i$ th such statistic equals the number of dyads in the network with exactly $\mathrm{d}[\mathrm{i}]$ shared partners.

## Usage

\# binary: ddsp(d, type="OTP")

## Arguments

```
d
a vector of distinct integers
type one of c("OTP", "ITP", "RTP", "OSP", "ISP")
```

## Note

This term can only be used with directed networks.
While there is only one shared partner configuration in the undirected case, nine distinct configurations are possible for directed graphs, selected using the type argument. Currently, terms may be defined with respect to five of these configurations; they are defined here as follows (using terminology from Butts (2008) and the relevent package):

- Outgoing Two-path ("OTP"): vertex $k$ is an OTP shared partner of ordered pair $(i, j)$ iff $i \rightarrow$ $k \rightarrow j$. Also known as "transitive shared partner".
- Incoming Two-path ("ITP"): vertex $k$ is an ITP shared partner of ordered pair $(i, j)$ iff $j \rightarrow$ $k \rightarrow i$. Also known as "cyclical shared partner"
- Reciprocated Two-path ("RTP"): vertex $k$ is an RTP shared partner of ordered pair $(i, j)$ iff $i \leftrightarrow k \leftrightarrow j$.
- Outgoing Shared Partner ("OSP"): vertex $k$ is an OSP shared partner of ordered pair $(i, j)$ iff $i \rightarrow k, j \rightarrow k$.
- Incoming Shared Partner ("ISP"): vertex $k$ is an ISP shared partner of ordered pair $(i, j)$ iff $k \rightarrow i, k \rightarrow j$. By default, outgoing two-paths ("OTP") are calculated. Note that Robins et al. (2009) define closely related statistics to several of the above, using slightly different terminology.

## See Also

ergmTerm for index of model terms currently visible to the package.
degcor-ergmTerm Degree Correlation

## Description

This term adds one network statistic equal to the correlation of the degrees of all pairs of nodes in the network which are tied. Only coded for undirected networks.

## Usage

\# binary: degcor

## See Also

ergmTerm for index of model terms currently visible to the package.

```
degcrossprod-ergmTerm Degree Cross-Product
```

## Description

This term adds one network statistic equal to the mean of the cross-products of the degrees of all pairs of nodes in the network which are tied. Only coded for undirected networks.

## Usage

\# binary: degcrossprod

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

This term adds one network statistic to the model for each element of from (or to ); the $i$ th such statistic equals the number of nodes in the network of degree greater than or equal to from[i] but strictly less than to[i], i.e. with edges in semiopen interval [from, to).

## Usage

\# binary: degrange(from, to=+Inf, by=NULL, homophily=FALSE, levels=NULL)

## Arguments

from, to vectors of distinct integers. If one of the vectors have length 1 , it is recycled to the length of the other. Otherwise, it must have the same length.
by, homophily the optional argument by specifies a vertex attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details). If this is specified and homophily is TRUE, then degrees are calculated using the subnetwork consisting of only edges whose endpoints have the same value of the by attribute. If by is specified and homophily is FALSE (the default), then separate degree range statistics are calculated for nodes having each separate value of the attribute.
levels TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)

## Details

This term can only be used with undirected networks; for directed networks see idegrange and odegrange. This term can be used with bipartite networks, and will count nodes of both first and second mode in the specified degree range. To count only nodes of the first mode ("actors"), use b1degrange and to count only those fo the second mode ("events"), use b2degrange .

## See Also

ergmTerm for index of model terms currently visible to the package.

```
degree-ergmTerm Degree
```

## Description

This term adds one network statistic to the model for each element in d ; the $i$ th such statistic equals the number of nodes in the network of degree $\mathrm{d}[\mathrm{i}]$, i.e. with exactly $\mathrm{d}[\mathrm{i}]$ edges. This term can only be used with undirected networks; for directed networks see idegree and odegree .

## Usage

\# binary: degree(d, by=NULL, homophily=FALSE, levels=NULL)

## Arguments

d vector of distinct integers
by, homophily the optional argument by specifies a vertex attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details). If this is specified and homophily is TRUE, then degrees are calculated using the subnetwork consisting of only edges whose endpoints have the same value of the by attribute. If by is specified and homophily is FALSE (the default), then separate degree range statistics are calculated for nodes having each separate value of the attribute.
levels TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)

## See Also

ergmTerm for index of model terms currently visible to the package.

```
degree1.5-ergmTerm Degree to the 3/2 power
```

## Description

This term adds one network statistic to the model equaling the sum over the actors of each actor's degree taken to the $3 / 2$ power (or, equivalently, multiplied by its square root). This term is an undirected analog to the terms of Snijders et al. (2010), equations (11) and (12). This term can only be used with undirected networks.

## Usage

\# binary: degree1.5

## See Also

ergmTerm for index of model terms currently visible to the package.
degreedist Computes and Returns the Degree Distribution Information for a Given Network

## Description

The degreedist generic computes and returns the degree distribution (number of vertices in the network with each degree value) for a given network. This help page documents the function. For help about the ERGM sample space constraint with that name, try help("degreedist-constraint").

## Usage

degreedist(object, ...)
\#\# S3 method for class 'network'
degreedist(object, print = TRUE, ...)

## Arguments

object a network object or some other object for which degree distribution is meaningful.
... Additional arguments to functions.
print logical, whether to print the degree distribution.

## Value

If directed, a matrix of the distributions of in and out degrees; this is row bound and only contains degrees for which one of the in or out distributions has a positive count. If bipartite, a list containing the degree distributions of b 1 and b 2 . Otherwise, a vector of the positive values in the degree distribution

## Methods (by class)

- network: Method for network objects.

## Examples

```
data(faux.mesa.high)
degreedist(faux.mesa.high)
```

```
degreedist-ergmConstraint
```

    Preserve the degree distribution of the given network
    
## Description

Only networks whose degree distributions are the same as those in the network passed in the model formula have non-zero probability.

## Usage

\# degreedist

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

```
degrees-ergmConstraint
```

Preserve the degree of each vertex of the given network

## Description

Only networks whose vertex degrees are the same as those in the network passed in the model formula have non-zero probability. If the network is directed, both indegree and outdegree are preserved.

## Usage

\# degrees
\# nodedegrees

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

```
density-ergmTerm Density
```

## Description

This term adds one network statistic equal to the density of the network. For undirected networks, density equals kstar (1) or edges divided by $n(n-1) / 2$; for directed networks, density equals edges or istar (1) or ostar (1) divided by $n(n-1)$.

## Usage

\# binary: density

## See Also

ergmTerm for index of model terms currently visible to the package.

```
desp-ergmTerm Directed edgewise shared partners
```

## Description

This term adds one network statistic to the model for each element in d where the $i$ th such statistic equals the number of edges in the network with exactly $\mathrm{d}[\mathrm{i}]$ shared partners.

## Usage

\# binary: desp(d, type="OTP")

## Arguments

d
type
a vector of distinct integers

```
one of c("OTP", "ITP", "RTP", "OSP", "ISP").
```

## Note

This term can only be used with directed networks.
While there is only one shared partner configuration in the undirected case, nine distinct configurations are possible for directed graphs, selected using the type argument. Currently, terms may be defined with respect to five of these configurations; they are defined here as follows (using terminology from Butts (2008) and the relevent package):

- Outgoing Two-path ("OTP"): vertex $k$ is an OTP shared partner of ordered pair $(i, j)$ iff $i \rightarrow$ $k \rightarrow j$. Also known as "transitive shared partner".
- Incoming Two-path ("ITP"): vertex $k$ is an ITP shared partner of ordered pair $(i, j)$ iff $j \rightarrow$ $k \rightarrow i$. Also known as "cyclical shared partner"
- Reciprocated Two-path ("RTP"): vertex $k$ is an RTP shared partner of ordered pair $(i, j)$ iff $i \leftrightarrow k \leftrightarrow j$.
- Outgoing Shared Partner ("OSP"): vertex $k$ is an OSP shared partner of ordered pair $(i, j)$ iff $i \rightarrow k, j \rightarrow k$.
- Incoming Shared Partner ("ISP"): vertex $k$ is an ISP shared partner of ordered pair $(i, j)$ iff $k \rightarrow i, k \rightarrow j$. By default, outgoing two-paths ("OTP") are calculated. Note that Robins et al. (2009) define closely related statistics to several of the above, using slightly different terminology.

## See Also

ergmTerm for index of model terms currently visible to the package.

## dgwdsp-ergmTerm Geometrically weighted dyadwise shared partner distribution

## Description

This term adds one network statistic to the model equal to the geometrically weighted dyadwise shared partner distribution with decay parameter decay parameter.

## Usage

\# binary: dgwdsp(decay, fixed=FALSE, cutoff=30, type="OTP")

## Arguments

| decay | nonnegative decay parameter for the shared partner or selected directed analogue <br> count; required if fixed=TRUE and ignored with a warning otherwise. |
| :--- | :--- |
| fixed | optional argument indicating whether the decay parameter is fixed at the given <br> value, or is to be fit as a curved exponential-family model (see Hunter and Hand- <br> cock, 2006). The default is FALSE, which means the scale parameter is not fixed <br> and thus the model is a curved exponential family. |
| cutoff | This optional argument sets the number of underlying DSP terms to use in com- <br> puting the statistics when fixed=FALSE, in order to reduce the computational <br> burden. Its default value can also be controlled by the gw. cutoff term option <br> control parameter. (See ?control.ergm.) <br> type$\quad$one of c("OTP", "ITP", "RTP", "OSP", "ISP") |

## Note

While there is only one shared partner configuration in the undirected case, nine distinct configurations are possible for directed graphs, selected using the type argument. Currently, terms may be defined with respect to five of these configurations; they are defined here as follows (using terminology from Butts (2008) and the relevent package):

- Outgoing Two-path ("OTP"): vertex $k$ is an OTP shared partner of ordered pair $(i, j)$ iff $i \rightarrow$ $k \rightarrow j$. Also known as "transitive shared partner".
- Incoming Two-path ("ITP"): vertex $k$ is an ITP shared partner of ordered pair $(i, j)$ iff $j \rightarrow$ $k \rightarrow i$. Also known as "cyclical shared partner"
- Reciprocated Two-path ("RTP"): vertex $k$ is an RTP shared partner of ordered pair $(i, j)$ iff $i \leftrightarrow k \leftrightarrow j$.
- Outgoing Shared Partner ("OSP"): vertex $k$ is an OSP shared partner of ordered pair $(i, j)$ iff $i \rightarrow k, j \rightarrow k$.
- Incoming Shared Partner ("ISP"): vertex $k$ is an ISP shared partner of ordered pair $(i, j)$ iff $k \rightarrow i, k \rightarrow j$. By default, outgoing two-paths ("OTP") are calculated. Note that Robins et al. (2009) define closely related statistics to several of the above, using slightly different terminology.

The GWDSP statistic is equal to the sum of GWNSP plus GWESP.
The decay parameter was called alpha prior to ergm 3.7.

## See Also

ergmTerm for index of model terms currently visible to the package.
dgwesp-ergmTerm Geometrically weighted edgewise shared partner distribution

## Description

This term adds a statistic equal to the geometrically weighted edgewise (not dyadwise) shared partner distribution with decay parameter decay parameter.

## Usage

\# binary: dgwesp(decay, fixed=FALSE, cutoff=30, type="OTP")

## Arguments

decay nonnegative decay parameter for the shared partner or selected directed analogue count; required if fixed=TRUE and ignored with a warning otherwise.
fixed optional argument indicating whether the decay parameter is fixed at the given value, or is to be fit as a curved exponential-family model (see Hunter and Handcock, 2006). The default is FALSE , which means the scale parameter is not fixed and thus the model is a curved exponential family.

```
cutoff This optional argument sets the number of underlying ESP terms to use in com-
                puting the statistics when fixed=FALSE, in order to reduce the computational
                burden. Its default value can also be controlled by the gw.cutoff term option
                control parameter. (See ?control.ergm.)
type
    one of c("OTP", "ITP", "RTP", "OSP", "ISP").
```

## Note

While there is only one shared partner configuration in the undirected case, nine distinct configurations are possible for directed graphs, selected using the type argument. Currently, terms may be defined with respect to five of these configurations; they are defined here as follows (using terminology from Butts (2008) and the relevent package):

- Outgoing Two-path ("OTP"): vertex $k$ is an OTP shared partner of ordered pair $(i, j)$ iff $i \rightarrow$ $k \rightarrow j$. Also known as "transitive shared partner".
- Incoming Two-path ("ITP"): vertex $k$ is an ITP shared partner of ordered pair $(i, j)$ iff $j \rightarrow$ $k \rightarrow i$. Also known as "cyclical shared partner"
- Reciprocated Two-path ("RTP"): vertex $k$ is an RTP shared partner of ordered pair $(i, j)$ iff $i \leftrightarrow k \leftrightarrow j$.
- Outgoing Shared Partner ("OSP"): vertex $k$ is an OSP shared partner of ordered pair $(i, j)$ iff $i \rightarrow k, j \rightarrow k$.
- Incoming Shared Partner ("ISP"): vertex $k$ is an ISP shared partner of ordered pair $(i, j)$ iff $k \rightarrow i, k \rightarrow j$. By default, outgoing two-paths ("OTP") are calculated. Note that Robins et al. (2009) define closely related statistics to several of the above, using slightly different terminology.

The decay parameter was called alpha prior to ergm 3.7.

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

This term is just like gwesp and gwdsp except it adds a statistic equal to the geometrically weighted nonedgewise (that is, over dyads that do not have an edge) shared partner distribution with decay parameter decay parameter.

## Usage

\# binary: dgwnsp(decay, fixed=FALSE, cutoff=30, type="OTP")

## Arguments

$$
\begin{array}{ll}
\text { decay } & \begin{array}{l}
\text { nonnegative decay parameter for the shared partner or selected directed analogue } \\
\text { count; required if fixed=TRUE and ignored with a warning otherwise. }
\end{array} \\
\text { fixed } & \begin{array}{l}
\text { optional argument indicating whether the decay parameter is fixed at the given } \\
\text { value, or is to be fit as a curved exponential-family model (see Hunter and Hand- } \\
\text { cock, 2006). The default is FALSE, which means the scale parameter is not fixed } \\
\text { and thus the model is a curved exponential family. }
\end{array} \\
\text { cutoff } & \begin{array}{l}
\text { This optional argument sets the number of underlying NSP terms to use in com- } \\
\text { puting the statistics when fixed=FALSE, in order to reduce the computational } \\
\text { burden. Its default value can also be controlled by the gw. cutoff term option } \\
\text { control parameter. (See ?control.ergm.) }
\end{array} \\
\text { type } & \text { one of c("OTP", "ITP", "RTP", "OSP", "ISP") }
\end{array}
$$

## Note

While there is only one shared partner configuration in the undirected case, nine distinct configurations are possible for directed graphs, selected using the type argument. Currently, terms may be defined with respect to five of these configurations; they are defined here as follows (using terminology from Butts (2008) and the relevent package):

- Outgoing Two-path ("OTP"): vertex $k$ is an OTP shared partner of ordered pair $(i, j)$ iff $i \rightarrow$ $k \rightarrow j$. Also known as "transitive shared partner".
- Incoming Two-path ("ITP"): vertex $k$ is an ITP shared partner of ordered pair $(i, j)$ iff $j \rightarrow$ $k \rightarrow i$. Also known as "cyclical shared partner"
- Reciprocated Two-path ("RTP"): vertex $k$ is an RTP shared partner of ordered pair $(i, j)$ iff $i \leftrightarrow k \leftrightarrow j$.
- Outgoing Shared Partner ("OSP"): vertex $k$ is an OSP shared partner of ordered pair $(i, j)$ iff $i \rightarrow k, j \rightarrow k$.
- Incoming Shared Partner ("ISP"): vertex $k$ is an ISP shared partner of ordered pair $(i, j)$ iff $k \rightarrow i, k \rightarrow j$. By default, outgoing two-paths ("OTP") are calculated. Note that Robins et al. (2009) define closely related statistics to several of the above, using slightly different terminology.

The decay parameter was called alpha prior to ergm 3.7.

## See Also

ergmTerm for index of model terms currently visible to the package.

## diff-ergmTerm Difference

## Description

For values of pow other than 0 , this term adds one network statistic to the model, equaling the sum, over directed edges $(i, j)$, of sign.action(attr[i]-attr[j])^pow if dir is "t-h" and of sign. action (attr[j]-attr[i])^pow if "h-t". That is, the argument dir determines which vertex's attribute is subtracted from which, with tail being the origin of a directed edge and head being its destination, and bipartite networks' edges being treated as going from the first part (b1) to the second (b2).
If pow $==0$, the exponentiation is replaced by the signum function: +1 if the difference is positive, 0 if there is no difference, and -1 if the difference is negative. Note that this function is applied after the sign.action. The comparison is exact, so when using calculated values of attr, ensure that values that you want to be considered equal are, in fact, equal.

## Usage

\# binary: diff(attr, pow=1, dir="t-h", sign.action="identity")
\# valued: diff(attr, pow=1, dir="t-h", sign.action="identity", form ="sum")

## Arguments

| at tr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) <br> exponent for the node difference |
| :--- | :--- |
| pow |  |
| dir | determines which vertix's attribute is subtracted from which. Accepts: "t-h" <br> (the default), "tail-head", "b1-b2", "h-t", "head-tail", and "b2-b1". <br> one of "identity", "abs", "posonly", "negonly". The following sign.actions <br> are possible: |
| • "identity" (the default) no transformation of the difference regardless of |  |
| sign |  |

## Note

this term may not be meaningful for unipartite undirected networks unless sign. action=="abs" . When used on such a network, it behaves as if all edges were directed, going from the lower-indexed vertex to the higher-indexed vertex.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
DiscUnif-ergmReference
```

## Discrete Uniform reference

## Description

Specifies each dyad's baseline distribution to be discrete uniform between a and $b$ (both inclusive): $h(y)=1$, with the support being $a, a+1, \ldots, b-1, b$.

## Usage

\# DiscUnif(a,b)

## Arguments

$\mathrm{a}, \mathrm{b} \quad$ minimum and maximum to the baseline discrete uniform distribution, both inclusive. Both values must be finite.

## See Also

ergmReference for index of reference distributions currently visible to the package.

```
dnsp-ergmTerm Directed non-edgewise shared partners
```

## Description

This term adds one network statistic to the model for each element in d where the $i$ th such statistic equals the number of non-edges in the network with exactly $\mathrm{d}[\mathrm{i}]$ shared partners.

## Usage

\# binary: dnsp(d, type="OTP")

## Arguments

d
type
a vector of distinct integers
one of c("OTP", "ITP", "RTP", "OSP", "ISP").

## Note

This term can only be used with directed networks.
While there is only one shared partner configuration in the undirected case, nine distinct configurations are possible for directed graphs, selected using the type argument. Currently, terms may be defined with respect to five of these configurations; they are defined here as follows (using terminology from Butts (2008) and the relevent package):

- Outgoing Two-path ("OTP"): vertex $k$ is an OTP shared partner of ordered pair $(i, j)$ iff $i \rightarrow$ $k \rightarrow j$. Also known as "transitive shared partner".
- Incoming Two-path ("ITP"): vertex $k$ is an ITP shared partner of ordered pair $(i, j)$ iff $j \rightarrow$ $k \rightarrow i$. Also known as "cyclical shared partner"
- Reciprocated Two-path ("RTP"): vertex $k$ is an RTP shared partner of ordered pair $(i, j)$ iff $i \leftrightarrow k \leftrightarrow j$.
- Outgoing Shared Partner ("OSP"): vertex $k$ is an OSP shared partner of ordered pair $(i, j)$ iff $i \rightarrow k, j \rightarrow k$.
- Incoming Shared Partner ("ISP"): vertex $k$ is an ISP shared partner of ordered pair $(i, j)$ iff $k \rightarrow i, k \rightarrow j$. By default, outgoing two-paths ("OTP") are calculated. Note that Robins et al. (2009) define closely related statistics to several of the above, using slightly different terminology.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
dsp-ergmTerm Dyadwise shared partners
```

## Description

This term adds one network statistic to the model for each element in d ; the $i$ th such statistic equals the number of dyads in the network with exactly $d[i]$ shared partners. This term can be used with directed and undirected networks.

## Usage

\# binary: dsp(d)

## Arguments

d
a vector of distinct integers

## Note

For directed networks, only outgoing two-path ("OTP") shared partners are counted. In other words, for a (directed) dyad ( $i, j$ ) in a directed graph, the number of shared partners counted by dsp is the number of nodes $k$ that have edges $i \rightarrow k \rightarrow>j$. (These may also be called homogeneous shared partners.) To count other types of shared partners instead, see ddsp.

## See Also

ergmTerm for index of model terms currently visible to the package.

## dyadcov-ergmTerm Dyadic covariate

## Description

This term adds three statistics to the model, each equal to the sum of the covariate values for all dyads occupying one of the three possible non-empty dyad states (mutual, upper-triangular asymmetric, and lower-triangular asymmetric dyads, respectively), with the empty or null state serving as a reference category. If the network is undirected, $x$ is either a matrix of edgewise covariates, or a network; if the latter, optional argument attrname provides the name of the edge attribute to use for edge values. This term adds one statistic to the model, equal to the sum of the covariate values for each edge appearing in the network. The edgecov and dyadcov terms are equivalent for undirected networks.

## Usage

\# binary: dyadcov(x, attrname=NULL)

## Arguments

$x$, attrname either a square matrix of covariates, one for each possible edge in the network, the name of a network attribute of covariates, or a network; if the latter, optional argument attrname provides the name of the quantitative edge attribute to use for covariate values (in this case, missing edges in $x$ are assigned a covariate value of zero).

## See Also

ergmTerm for index of model terms currently visible to the package.

```
dyadnoise-ergmConstraint
```

A soft constraint to adjust the sampled distribution for dyad-level noise with known perturbation probabilities

## Description

It is assumed that the observed LHS network is a noisy observation of some unobserved true network, with p01 giving the dyadwise probability of erroneously observing a tie where the true network had a non-tie and p10 giving the dyadwise probability of erroneously observing a nontie where the true network had a tie.

## Usage

\# dyadnoise(p01, p10)

## Arguments

p01, p10 can both be scalars or both be adjacency matrices of the same dimension as that of the LHS network giving these probabilities.

## Note

See Karwa et al. (2016) for an application.

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

## Description

This is an "operator" constraint that takes one or two ergmTerm dyad-independent formulas. For the terms in the vary= formula, only those that change at least one of the terms will be allowed to vary, and all others will be fixed. If both formulas are given, the dyads that vary either for one or for the other will be allowed to vary. Note that a formula passed to Dyads without an argument name will default to fix=.

## Usage

\# Dyads(fix=NULL, vary=NULL)

## Arguments

fix, vary formula with only dyad-independent terms

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

## Description

This network data set comprises two versions of a biological network in which the nodes are operons in Escherichia Coli and a directed edge from one node to another indicates that the first encodes the transcription factor that regulates the second.

## Usage <br> data(ecoli)

## Details

The network object ecoli1 is directed, with 423 nodes and 519 arcs. The object ecoli2 is an undirected version of the same network, in which all arcs are treated as edges and the five isolated nodes (which exhibit only self-regulation in ecoli1) are removed, leaving 418 nodes.

## Licenses and Citation

When publishing results obtained using this data set, the original authors (Salgado et al, 2001; Shen-Orr et al, 2002) should be cited, along with this R package.

## Source

The data set is based on the RegulonDB network (Salgado et al, 2001) and was modified by ShenOrr et al (2002).

edgecov-ergmTerm Edge covariate

## Description

This term adds one statistic to the model, equal to the sum of the covariate values for each edge appearing in the network. The edgecov term applies to both directed and undirected networks. For undirected networks the covariates are also assumed to be undirected. The edgecov and dyadcov terms are equivalent for undirected networks.

## Usage

\# binary: edgecov(x, attrname=NULL)
\# valued: edgecov(x, attrname=NULL, form="sum")

## Arguments

$x$, attrname either a square matrix of covariates, one for each possible edge in the network, the name of a network attribute of covariates, or a network; if the latter, optional argument attrname provides the name of the quantitative edge attribute to use for covariate values (in this case, missing edges in $x$ are assigned a covariate value of zero).
form character how to aggregate tie values in a valued ERGM

## See Also

ergmTerm for index of model terms currently visible to the package.
edges-ergmConstraint Preserve the edge count of the given network

## Description

Only networks having the same number of edges as the network passed in the model formula have non-zero probability.

## Usage

\# edges

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

```
    edges-ergmTerm Number of edges in the network
```

## Description

This term adds one network statistic equal to the number of edges (i.e. nonzero values) in the network. For undirected networks, edges is equal to $\operatorname{kstar}(1)$; for directed networks, edges is equal to both ostar(1) and istar(1).

## Usage

\# binary: edges
\# valued: nonzero
\# valued: edges

## See Also

ergmTerm for index of model terms currently visible to the package.

```
egocentric-ergmConstraint
```

Preserve values of dyads incident on vertices with given attribute

## Description

Preserve values of dyads incident on vertices with attribute attr being TRUE or if at trname is NULL , the vertex attribute "na" being FALSE.

## Usage

\# egocentric(attr=NULL, direction="both")

## Arguments

attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.)
direction one of "both", "out" and "in", only applies to directed networks. "out" only preserves the out-dyads of those actors and "in" preserves their in-dyads.

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

```
enformulate.curved-deprecated
```

Convert a curved ERGM into a form suitable as initial values for the same ergm. Deprecated in 4.0.0.

## Description

The generic enformulate. curved converts an ergm object or formula of a model with curved terms to the variant in which the curved parameters embedded into the formula and are removed from the parameter vector. This is the form that used to be required by ergm calls.

## Usage

enformulate.curved(object, ...)
\#\# S3 method for class 'ergm'
enformulate.curved(object, ...)
\#\# S3 method for class 'formula'
enformulate.curved(object, theta, ...)

## Arguments

object An ergm object or an ERGM formula. The curved terms of the given formula (or the formula used in the fit) must have all of their arguments passed by name.
... Unused at this time.
theta Curved model parameter configuration.

## Details

Because of a current kludge in ergm, output from one run cannot be directly passed as initial values (control.ergm(init=)) for the next run if any of the terms are curved. One workaround is to embed the curved parameters into the formula (while keeping fixed=FALSE) and remove them from control.ergm(init=).
This function automates this process for curved ERGM terms included with the ergm package. It does not work with curved terms not included in ergm.

## Value

A list with the following components:

| formula | The formula with curved parameter estimates incorporated. |
| :--- | :--- |
| theta | The coefficient vector with curved parameter estimates removed. |

## See Also

ergm, simulate.ergm
equalto-ergmTerm Number of dyads with values equal to a specific value (within tolerance)

## Description

Adds one statistic equal to the number of dyads whose values are within tolerance of value , i.e., between value-tolerance and value+tolerance, inclusive.

## Usage

\# valued: equalto(value=0, tolerance=0)

## Arguments

```
value numerical threshold
tolerance numerical threshold
```

## See Also

ergmTerm for index of model terms currently visible to the package.

```
ergm Exponential-Family Random Graph Models
```

## Description

ergm is used to fit exponential-family random graph models (ERGMs), in which the probability of a given network, $y$, on a set of nodes is $h(y) \exp \{\eta(\theta) \cdot g(y)\} / c(\theta)$, where $h(y)$ is the reference measure (usually $h(y)=1$ ), $g(y)$ is a vector of network statistics for $y, \eta(\theta)$ is a natural parameter vector of the same length (with $\eta(\theta)=\theta$ for most terms), and $c(\theta)$ is the normalizing constant for the distribution. ergm can return a maximum pseudo-likelihood estimate, an approximate maximum likelihood estimate based on a Monte Carlo scheme, or an approximate contrastive divergence estimate based on a similar scheme. (For an overview of the package, see ergm-package.)

## Usage

ergm(
formula,
response = NULL,
reference = ~Bernoulli,
constraints $=\sim$.,
obs.constraints = ~. - observed,
offset.coef = NULL,
target.stats = NULL,

```
    eval.loglik = getOption("ergm.eval.loglik"),
    estimate = c("MLE", "MPLE", "CD"),
    control = control.ergm(),
    verbose = FALSE,
    ...,
    basis = ergm.getnetwork(formula)
)
is.ergm(object)
## S3 method for class 'ergm'
nobs(object, ...)
## S3 method for class 'ergm'
print(x, digits = max(3, getOption("digits") - 3), ...)
## S3 method for class 'ergm'
vcov(object, sources = c("all", "model", "estimation"), ...)
```

## Arguments

formula | An R formula object, of the form y ~ <model terms>, where y is a network |
| :--- |
| object or a matrix that can be coerced to a network object. For the details on |
| the possible <model terms>, see ergmTerm and Morris, Handcock and Hunter |
| (2008) for binary ERGM terms and Krivitsky (2012) for valued ERGM terms |
| (terms for weighted edges). To create a network object in R, use the network() |
| function, then add nodal attributes to it using the \%v\% operator if necessary. En- |
| closing a model term in offset() fixes its value to one specified in offset. coef. |
| (A second argument-a logical or numeric index vector-can be used to select |
| which of the parameters within the term are offsets.) |
| Either a character string, a formula, or NULL (the default), to specify the response |
| attributes and whether the ERGM is binary or valued. Interpreted as follows: |
| NULL Model simple presence or absence, via a binary ERGM. |
| character string The name of the edge attribute whose value is to be modeled. |
| Type of ERGM will be determined by whether the attribute is logical |
| (TRUE/FALSE) for binary or numeric for valued. |
| response |
| a formula must be of the form NAME~EXPR\|TYPE (with | being literal). EXPR is |
| evaluated in the formula's environment with the network's edge attributes |
| accessible as variables. The optional NAME specifies the name of the edge |
| attribute into which the results should be stored, with the default being a |
| concise version of EXPR. Normally, the type of ERGM is determined by |
| whether the result of evaluating EXPR is logical or numeric, but the optional |

TYPE can be used to override by specifying a scalar of the type involved
(e.g., TRUE for binary and for valued).
on the right-hand side. Multiple constraints may be given, separated by " + " and "-" operators. (See ERGM constraints for the explanation of their semantics.) Together with the model terms in the formula and the reference measure, the constraints define the distribution of networks being modeled.
It is also possible to specify a proposal function directly either by passing a string with the function's name (in which case, arguments to the proposal should be specified through the prop.args argument to control.ergm) or by giving it on the LHS of the constraints formula, in which case it will override the one chosen automatically.
The default is $\sim$., for an unconstrained model.
See the ERGM constraints documentation for the constraints implemented in the ergm package. Other packages may add their own constraints.
Note that not all possible combinations of constraints and reference measures are supported. However, for relatively simple constraints (i.e., those that simply permit or forbid specific dyads or sets of dyads from changing), arbitrary combinations should be possible.
obs.constraints
A one-sided formula specifying one or more constraints or other modification in addition to those specified by constraints that had affected the observation process for the network, using syntax similar to the formula argument. Multiple constraints may be given, separated by " + " operators.
This allows the domain of the integral in the numerator of the partially obseved network face-value likelihoods of Handcock and Gile (2010) and Karwa et al. (2017) to be specified explicitly.

The default is $\sim$ observed, to constrain the integral to only integrate over the missing dyads. (It is dropped automatically if the network is completely observed.)
It is also possible to specify a proposal function directly by passing a string with the function's name. In that case, arguments to the proposal should be specified through the obs.prop.args argument to control.ergm.
See the ERGM constraints documentation for the constraints implemented in the ergm package. Other packages may add their own constraints.
Note that not all possible combinations of constraints and reference measures are supported.
offset.coef A vector of coefficients for the offset terms.
target.stats vector of "observed network statistics," if these statistics are for some reason different than the actual statistics of the network on the left-hand side of formula. Equivalently, this vector is the mean-value parameter values for the model. If this is given, the algorithm finds the natural parameter values corresponding to these mean-value parameters. If NULL, the mean-value parameters used are the observed statistics of the network in the formula.
eval.loglik Logical: For dyad-dependent models, if TRUE, use bridge sampling to evaluate the log-likelihoood associated with the fit. Has no effect for dyad-independent models. Since bridge sampling takes additional time, setting to FALSE may speed performance if likelihood values (and likelihood-based values like AIC and BIC) are not needed. Can be set globally via option(ergm.eval.loglik=...), which is set to TRUE when the package is loaded. (See options?ergm.)

| estimate | If "MPLE," then the maximum pseudolikelihood estimator is returned. If "MLE" <br> (the default), then an approximate maximum likelihood estimator is returned. <br> For certain models, the MPLE and MLE are equivalent, in which case this ar- <br> gument is ignored. (To force MCMC-based approximate likelihood calculation <br> even when the MLE and MPLE are the same, see the force.main argument <br> of control.ergm. If "CD" (EXPERIMENTAL), the Monte-Carlo contrastive <br> divergence estimate is returned.) |
| :--- | :--- |
| A list of control parameters for algorithm tuning, typically constructed with |  |
| control.ergm(). Its documentation gives the the list of recognized control pa- |  |
| rameters and their meaning. The more generic utility snctrl() (StatNet Con- |  |
| control |  |
| TRoL) also provides argument completion for the available control functions |  |
| and limited argument name checking. |  |
| verbose | A logical or an integer to control the amount of progress and diagnostic in- <br> formation to be printed. FALSE/0 produces minimal output, wit higher values <br> producing more detail. Note that very high values (5+) may significantly slow <br> down processing. |
| Addional arguments, to be passed to lower-level functions. |  |
| basis | a value (usually a network) to override the LHS of the formula. |
| object | an ergm object. |
| x, digits | See print(). <br> Automatically called when an object of class ergm is printed. Currently, sum- <br> marizes the size of the MCMC sample, the $\theta$ vector governing the selection of |
| the sample, and the Monte Carlo MLE. The optional digits argument specifies |  |
| the significant digits for coefficients |  |

## Value

ergm returns an object of class ergm that is a list consisting of the following elements:
coef The Monte Carlo maximum likelihood estimate of $\theta$, the vector of coefficients for the model parameters.
sample The $n \times p$ matrix of network statistics, where $n$ is the sample size and $p$ is the number of network statistics specified in the model, generated by the last iteration of the MCMC-based likelihood maximization routine. These statistics are centered with respect to the observed statistics or target. stats, unless missing data MLE is used.
sample.obs As sample, but for the constrained sample.
iterations The number of Newton-Raphson iterations required before convergence.
MCMCtheta The value of $\theta$ used to produce the Markov chain Monte Carlo sample. As long as the Markov chain mixes sufficiently well, sample is roughly a random sample from the distribution of network statistics specified by the model with the parameter equal to MCMC theta. If estimate="MPLE" then MCMCtheta equals the MPLE.

| loglikelihood | The approximate change in log-likelihood in the last iteration. The value is only approximate because it is estimated based on the MCMC random sample. |
| :---: | :---: |
| gradient | The value of the gradient vector of the approximated loglikelihood function, evaluated at the maximizer. This vector should be very close to zero. |
| covar | Approximate covariance matrix for the MLE, based on the inverse Hessian of the approximated loglikelihood evaluated at the maximizer. |
| failure | Logical: Did the MCMC estimation fail? |
| network | Network passed on the left-hand side of formula. If target. stats are passed, it is replaced by the network returned by $\operatorname{san}()$. |
| newnetworks | A list of the final networks at the end of the MCMC simulation, one for each thread. |
| newnetwork | The first (possibly only) element of newnetworks. |
| coef.init | The initial value of $\theta$. |
| est.cov | The covariance matrix of the model statistics in the final MCMC sample. |
| coef.hist, steplen.hist, stats.hist, stats.obs.hist |  |
|  | For the MCMLE method, the history of coefficients, Hummel step lengths, and average model statistics for each iteration.. |
| control | The control list passed to the call. |
| etamap | The set of functions mapping the true parameter theta to the canonical parameter eta (irrelevant except in a curved exponential family model) |
| formula | The original formula entered into the ergm function. |
| target.stats | The target.stats used during estimation (passed through from the Arguments) |
| target.esteq | Used for curved models to preserve the target mean values of the curved terms. It is identical to target.stats for non-curved models. |
| constrained | The list of constraints implied by the constraints used by original ergm call |
| constraints | Constraints used during estimation (passed through from the Arguments) |
| reference | The reference measure used during estimation (passed through from the Arguments) |
| estimate | The estimation method used (passed through from the Arguments). |
| offset | vector of logical telling which model parameters are to be set at a fixed value (i.e., not estimated). |
| drop | If control\$drop=TRUE, a numeric vector indicating which terms were dropped due to to extreme values of the corresponding statistics on the observed network, and how: |
|  | 0 The term was not dropped. |
|  | -1 The term was at its minimum and the coefficient was fixed at -Inf. |
|  | +1 The term was at its maximum and the coefficient was fixed at + Inf. |
| estimable | A logical vector indicating which terms could not be estimated due to a constraints constraint fixing that term at a constant value. |
| null.lik | Log-likelihood of the null model. Valid only for unconstrained models. |
| mle.lik | The approximate log-likelihood for the MLE. The value is only approximate because it is estimated based on the MCMC random sample. |

## Methods (by generic)

- nobs: Return the number of informative dyads of a model fit.
- print:
- vcov: extracts the variance-covariance matrix of parameter estimates.

## Notes on model specification

Although each of the statistics in a given model is a summary statistic for the entire network, it is rarely necessary to calculate statistics for an entire network in a proposed Metropolis-Hastings step. Thus, for example, if the triangle term is included in the model, a census of all triangles in the observed network is never taken; instead, only the change in the number of triangles is recorded for each edge toggle.
In the implementation of ergm, the model is initialized in $R$, then all the model information is passed to a $C$ program that generates the sample of network statistics using MCMC. This sample is then returned to R, which implements a simple Newton-Raphson algorithm to approximate the MLE. An alternative style of maximum likelihood estimation is to use a stochastic approximation algorithm. This can be chosen with the control.ergm(style="Robbins-Monro") option.

The mechanism for proposing new networks for the MCMC sampling scheme, which is a MetropolisHastings algorithm, depends on two things: The constraints, which define the set of possible networks that could be proposed in a particular Markov chain step, and the weights placed on these possible steps by the proposal distribution. The former may be controlled using the constraints argument described above. The latter may be controlled using the prop.weights argument to the control. ergm function.

The package is designed so that the user could conceivably add additional proposal types.

ergm-options

Global options and term options for the ergm package

## Description

Options set via the built-in options() functions that affect ergm estimation and options that control the behavior of some terms.

## Global options and defaults

ergm.eval.loglik = TRUE Whether ergm() and similar functions will evaluate the likelihood of the fitted model. Can be overridden for a specific call by passing eval.loglik argument directly.
ergm. loglik.warn_dyads = TRUE Whether log-likelihood evaluation should issue a warning when the effective number of dyads that can vary in the sample space is poorly defined, such as if the degree sequence is constrained.
ergm.cluster.retries = 5 ergm's parallel routines implement rudimentary fault-tolerance. This option controls the number of retries for a cluster call before giving up.
ergm.term $=$ list() The default term options below.

## Term options

Term options can be set in three places, in the order of precedence from high to low:

1. As a term argument (not always). For example, gw. cutoff below can be set in a gwesp term by gwesp(..., cutoff=X).
2. For functions such as summary that take ergm formulas but do not take a control list, the named arguments passed in as . ... E.g, summary (nw $\sim$ gwesp(.5,fix=TRUE), gw.cutoff=60) will evaluate the GWESP statistic with its cutoff set to 60.
3. As an element in a term. options= list passed via a control function such as control.ergm() or, for functions that do not, in a list with that argument name. E.g., summary (nw~gwesp(.5,fix=TRUE), term.options=list(gw.cutoff=60)) has the same effect.
4. As an element in a global option list ergm. term above.

The following options are in use by terms in the ergm package:
version A string that can be interpreted as an $R$ package version. If set, the term will attempt to emulate its behavior as it was that version of ergm. Not all past version behaviors are available.
gw. cutoff In geometrically weighted terms (gwesp, gwdegree, etc.) the highest number of shared partners, degrees, etc. for which to compute the statistic. This usually defaults to 30 .
cache.sp Whether the gwesp, dgwesp, and similar terms need should use a cache for the dyadwise number of shared partners. This usually improves performance significantly and therefore defaults to TRUE, but it can be disabled.
interact. dependent Whether to allow and how to handle the user attempting to interact dyaddependent terms (e.g., absdiff("age"): triangles or absdiff("age")*triangles as opposed to absdiff("age"): nodefactor("sex")). Possible values are "error" (the default), "message", and "warning", for their respective actions, and "silent" for simply processing the term.
ergm-parallel Parallel Processing in the ergm Package

## Description

Using clusters multiple CPUs or CPU cores to speed up ERGM estimation and simulation.
The ergm.getCluster function is usually called internally by the ergm process (in ergm_MCMC_sample) and will attempt to start the appropriate type of cluster indicated by the control.ergm settings. It will also check that the same version of ergm is installed on each node.

The ergm. stopCluster shuts down a cluster, but only if ergm.getCluster was responsible for starting it.
The ergm.restartCluster restarts and returns a cluster, but only if ergm.getCluster was responsible for starting it.
nthreads is a simple generic to obtain the number of parallel processes represented by its argument, keeping in mind that having no cluster (e.g., NULL) represents one thread.

## Usage

ergm.getCluster (control $=$ NULL, verbose $=$ FALSE, stop_on_exit $=$ parent.frame())
ergm.stopCluster(..., verbose $=$ FALSE)
ergm. restartCluster (control $=$ NULL, verbose $=$ FALSE)
set.MT_terms(n)

```
get.MT_terms()
nthreads(clinfo = NULL, ...)
## S3 method for class 'cluster'
nthreads(clinfo = NULL, ...)
## S3 method for class '`NULL`'
nthreads(clinfo = NULL, ...)
## S3 method for class 'control.list'
nthreads(clinfo = NULL, ...)
```

## Arguments

| control | a control.ergm (or similar) list of parameter values from which the parallel <br> settings should be read; can also be NULL, in which case an existing cluster is <br> used if started, or no cluster otherwise. |
| :--- | :--- |
| verbose | A logical or an integer to control the amount of progress and diagnostic in- <br> formation to be printed. FALSE/0 produces minimal output, wit higher values <br> producing more detail. Note that very high values (5+) may significantly slow <br> down processing. |
| stop_on_exit | An environment or NULL. If an environment, defaulting to that of the calling <br> function, the cluster will be stopped when the calling the frame in question exits. |
| $\ldots$ | not currently used <br> an integer specifying the number of threads to use; 0 (the starting value) disables <br> multithreading, and -1 or NA sets it to the number of CPUs detected. |
| clinfo | a cluster or another object. |

## Details

For estimation that require MCMC, ergm can take advantage of multiple CPUs or CPU cores on the system on which it runs, as well as computing clusters through one of two mechanisms:

Running MCMC chains in parallel Packages parallel and snow are used to to facilitate this, all cluster types that they support are supported.
The number of nodes used and the parallel API are controlled using the parallel and parallel.type arguments passed to the control functions, such as control.ergm().
The ergm.getCluster() function is usually called internally by the ergm process (in ergm_MCMC_sample())
and will attempt to start the appropriate type of cluster indicated by the control.ergm() set-
tings. The ergm. stopCluster () is helpful if the user has directly created a cluster.
Further details on the various cluster types are included below.
Multithreaded evaluation of model terms Rather than running multiple MCMC chains, it is possible to attempt to accelerate sampling by evaluating qualified terms' change statistics in multiple threads run in parallel. This is done using the OpenMP API.
However, this introduces a nontrivial amont of computational overhead. See below for a list of the major factors affecting whether it is worthwhile.

Generally, the two approaches should not be used at the same time without caution. In particular, by default, cluster slave nodes will not "inherit" the multithreading setting; but parallel.inherit.MT= control parameter can override that. Their relative advantages and disadvantages are as follows:

- Multithreading terms cannot take advantage of clusters but only of CPUs and cores.
- Parallel MCMC chains produce several independent chains; multithreading still only produces one.
- Multithreading terms actually accellerates sampling, including the burn-in phase; parallel MCMC's multiple burn-in runs are effectively "wasted".

## Value

set. MT_terms() returns the previous setting, invisibly.
get. MT_terms() returns the current setting.

## Different types of clusters

PSOCK clusters The parallel package is used with PSOCK clusters by default, to utilize multiple cores on a system. The number of cores on a system can be determined with the detectCores() function.
This method works with the base installation of R on all platforms, and does not require additional software.
For more advanced applications, such as clusters that span multiple machines on a network, the clusters can be initialized manually, and passed into ergm() and others using the parallel control argument. See the second example below.
MPI clusters To use MPI to accelerate ERGM sampling, pass the control parameter parallel.type="MPI". ergm requires the snow and Rmpi packages to communicate with an MPI cluster.
Using MPI clusters requires the system to have an existing MPI installation. See the MPI documentation for your particular platform for instructions.
To use ergm() across multiple machines in a high performance computing environment, see the section "User initiated clusters" below.
User initiated clusters A cluster can be passed into ergm() with the parallel control parameter. ergm() will detect the number of nodes in the cluster, and use all of them for MCMC sampling. This method is flexible: it will accept any cluster type that is compatible with snow or parallel packages.

## When is multithreading terms worthwhile?

- The more terms with statistics the model has, the more benefit from parallel execution.
- The more expensive the terms in the model are, the more benefit from parallel execution. For example, models with terms like gwdsp will generally get more benefit than models where all terms are dyad-independent.
- Sampling more dense networks will generally get more benefit than sparse networks. Network size has little, if any, effect.
- More CPUs/cores usually give greater speed-up, but only up to a point, because the amount of overhead grows with the number of threads; it is often better to "batch" the terms into a smaller number of threads than possible.
- Any other workload on the system will have a more severe effect on multithreaded execution. In particular, do not run more threads than CPUs/cores that you want to allocate to the tasks.
- Under Windows, even compiling with OpenMP appears to introduce unacceptable amounts of overhead, so it is disabled for Windows at compile time. To enable, delete src/Makevars .win and recompile from scratch.

## Note

The this is a setting global to the ergm package and all of its $C$ functions, including when called from other packages via the Linking-To mechanism.

## Examples

```
# Uses 2 SOCK clusters for MCMLE estimation
data(faux.mesa.high)
nw <- faux.mesa.high
fauxmodel.01 <- ergm(nw ~ edges + isolates + gwesp(0.2, fixed=TRUE),
    control=control.ergm(parallel=2, parallel.type="PSOCK"))
summary(fauxmodel.01)
```

## Description

ergm.allstats produces a matrix of network statistics for an arbitrary statnet exponential-family random graph model. One possible use for this function is to calculate the exact loglikelihood function for a small network via the ergm. exact function.

## Usage

```
ergm.allstats(
    formula,
    zeroobs = TRUE,
    force = FALSE,
    maxNumChangeStatVectors = 2^16,
    )
```

## Arguments

formula an formula object of the form $\mathrm{y} \sim$ <model terms>, where y is a network object or a matrix that can be coerced to a network object. For the details on the possible <model terms>, see ergmTerm. To create a network object in, use the network() function, then add nodal attributes to it using the \%v\% operator if necessary.
zeroobs Logical: Should the vectors be centered so that the network passed in the formula has the zero vector as its statistics?
force Logical: Should the algorithm be run even if it is determined that the problem may be very large, thus bypassing the warning message that normally terminates the function in such cases?
maxNumChangeStatVectors
Maximum possible number of distinct values of the vector of statistics. It's good to use a power of 2 for this.
... further arguments; not currently used.

## Details

The mechanism for doing this is a recursive algorithm, where the number of levels of recursion is equal to the number of possible dyads that can be changed from 0 to 1 and back again. The algorithm starts with the network passed in formula, then recursively toggles each edge twice so that every possible network is visited.
ergm.allstats should only be used for small networks, since the number of possible networks grows extremely fast with the number of nodes. An error results if it is used on a directed network of more than 6 nodes or an undirected network of more than 8 nodes; use force=TRUE to override this error.

## Value

Returns a list object with these two elements:

$$
\begin{array}{ll}
\text { weights } & \begin{array}{l}
\text { integer of counts, one for each row of statmat telling how many networks share } \\
\text { the corresponding vector of statistics. }
\end{array} \\
\text { statmat } & \text { matrix in which each row is a unique vector of statistics. }
\end{array}
$$

ergm.exact

## Examples

```
# Count by brute force all the edge statistics possible for a 7-node
# undirected network
mynw <- network(matrix(0,7,7),dir=FALSE)
system.time(a <- ergm.allstats(mynw~edges))
# Summarize results
rbind(t(a$statmat),a$weights)
```

```
# Each value of a$weights is equal to 21-choose-k,
# where k is the corresponding statistic (and 21 is
# the number of dyads in an 7-node undirected network).
# Here's a check of that fact:
as.vector(a$weights - choose(21, t(a$statmat)))
# Simple ergm.exact outpuf for this network.
# We know that the loglikelihood for my empty 7-node network
# should simply be -21*log(1+exp(eta)), so we may check that
# the following two values agree:
-21*log(1+exp(.1234))
ergm.exact(.1234, mynw~edges, statmat=a$statmat, weights=a$weights)
```

ergm.bridge.1lr Bridge sampling to evaluate ERGM log-likelihoods and log-likelihood ratios

## Description

ergm.bridge. llr uses bridge sampling with geometric spacing to estimate the difference between the log-likelihoods of two parameter vectors for an ERGM via repeated calls to simulate. formula. ergm. ergm.bridge. 0.11 k is a convenience wrapper that returns the log-likelihood of configuration $\theta$ relative to the reference measure. That is, the configuration with $\theta=0$ is defined as having loglikelihood of 0 .
ergm.bridge.dindstart. 11 k is a wrapper that uses a dyad-independent ERGM as a starting point for bridge sampling to estimate the log-likelihood for a given dyad-dependent model and parameter configuration. Note that it only handles binary ERGMs (response=NULL) and with constraints (constraints=) that that do not induce dyadic dependence.

## Usage

```
ergm.bridge.llr(
    object,
    response \(=\) NULL,
    reference \(=\sim\) Bernoulli,
    constraints \(=\sim\).,
    from,
    to,
    obs.constraints \(=\sim\). - observed,
    target.stats = NULL,
    basis = ergm.getnetwork(object),
    verbose = FALSE,
    llronly = FALSE,
    control = control.ergm.bridge()
)
```

```
ergm.bridge.0.11k(
    object,
    response = NULL,
    reference \(=\sim\) Bernoulli,
    coef,
    ...,
    llkonly = TRUE,
    control = control.ergm.bridge(),
    basis = ergm.getnetwork(object)
)
ergm.bridge.dindstart.llk(
    object,
    response = NULL,
    constraints \(=\sim\).,
    coef,
    obs.constraints \(=\sim\). - observed,
    target.stats \(=\) NULL,
    dind = NULL,
    coef.dind = NULL,
    basis = ergm.getnetwork(object),
    ...,
    llkonly = TRUE,
    control = control.ergm.bridge(),
    verbose = FALSE
)
```

## Arguments

object
response
reference A one-sided formula specifying the reference measure $(h(y)$ ) to be used. (Defaults to ~Bernoulli.)

|  | One-sided formulas specifying one or more constraints on the support of the distribution of the networks being simulated and on the observation process respectively. See the documentation for a similar argument for ergm for more information. |
| :---: | :---: |
| from, to | The initial and final parameter vectors. |
| target.stats | A vector of sufficient statistics to be used in place of those of the network in the formula. |
| basis | An optional network object to start the Markov chain. If omitted, the default is the left-hand-side of the object. |
| verbose | A logical or an integer to control the amount of progress and diagnostic information to be printed. FALSE/0 produces minimal output, wit higher values producing more detail. Note that very high values (5+) may significantly slow down processing. |
|  | Further arguments to ergm. bridge.llr and simulate.formula.ergm. |
| llronly | Logical: If TRUE, only the estiamted log-ratio will be returned by ergm. bridge.llr. |
| control | A list of control parameters for algorithm tuning, typically constructed with control.ergm.bridge(). Its documentation gives the the list of recognized control parameters and their meaning. The more generic utility snctrl() (StatNet ConTRoL) also provides argument completion for the available control functions and limited argument name checking. |
| coef | A vector of coefficients for the configuration of interest. |
| llkonly | Whether only the estiamted log-likelihood should be returned by the ergm.bridge.0.1lk and ergm.bridge.dindstart.llk. (Defaults to TRUE.) |
| dind | A one-sided formula with the dyad-independent model to use as a starting point. Defaults to the dyad-independent terms found in the formula object with an overal density term (edges) added if not redundant. |
| coef.dind | Parameter configuration for the dyad-independent starting point. Defaults to the MLE of dind. |

## Value

If llronly=TRUE or llkonly=TRUE, these functions return the scalar log-likelihood-ratio or the log-likelihood. Otherwise, they return a list with the following components:

| llr | The estimated log-ratio. |
| :--- | :--- |
| llr.vcov | The estimated variance of the log-ratio due to MCMC approximation. |
| llrs | A list of lists (1 per attempt) of the estimated log-ratios for each of the bridge.nsteps <br> bridges. |
| llrs.vcov | A list of lists (1 per attempt) of the estimated variances of the estimated log- <br> ratios for each of the bridge.nsteps bridges. |
| paths | A list of lists (1 per attempt) with two elements: theta, a numeric matrix with <br> bridge.nsteps rows, with each row being the respective bridge's parameter <br> configuration; and weight, a vector of length bridge.nsteps containing its <br> weight. |

Dtheta.Du The gradient vector of the parameter values with respect to position of the bridge.
ergm.bridge.0.1lk result list also includes an llk element, with the log-likelihood itself (with the reference distribution assumed to have likelihood 0 ).
ergm.bridge.dindstart. 11 k result list also includes an llk element, with the log-likelihood itself and an llk.dind element, with the log-likelihood of the nearest dyad-independent model.

```

ergm. design Obtain the set of informative dyads based on the network structure.

## Description

Note that this function is not recommended for general use, since it only supports only one way of specifying observational structure-through NA edges. It is likely to be deprecated in the future.

## Usage

ergm.design(nw, ...)

## Arguments

| nw | a network object. |
| :--- | :--- |
| $\ldots$ | term options. |

## Value

ergm. design returns a rlebdm of informative (non-missing, non fixed) dyads.

## Description

ergm.exact calculates the exact loglikelihood, evaluated at eta, for the statnet exponentialfamily random graph model represented by formula.

## Usage

ergm.exact(eta, formula, statmat = NULL, weights = NULL, ...)

## Arguments

eta vector of canonical parameter values at which the loglikelihood should be evaluated.
formula an link\{formula\} object of the form $\mathrm{y} \sim$ <model terms>, where y is a network object or a matrix that can be coerced to a network object. For the details on the possible <model terms>, see ergmTerm. To create a network object in, use the network () function, then add nodal attributes to it using the $\% \mathrm{v} \%$ operator if necessary.
statmat if NULL, call ergm.allstats to generate all possible graph statistics for the networks in this model.
weights In case statmat is not NULL, this should be the vector of counts corresponding to the rows of statmat. If statmat is NULL, this is generated by the call to ergm.allstats.
... further arguments; not currently used.

## Details

ergm. exact should only be used for small networks, since the number of possible networks grows extremely fast with the number of nodes. An error results if it is used on a directed network of more than 6 nodes or an undirected network of more than 8 nodes; use force=TRUE to override this error.

In case this function is to be called repeatedly, for instance by an optimization routine, it is preferable to call ergm.allstats first, then pass statmat and weights explicitly to avoid repeatedly calculating these objects.

## Value

Returns the value of the exact loglikelihood, evaluated at eta, for the statnet exponential-family random graph model represented by formula.

    system.time(a <- ergm.allstats(mynw~edges))
    # Summarize results
    rbind(t(a$statmat),a$weights)
    # Each value of a$weights is equal to 21-choose-k,
    # where k is the corresponding statistic (and 21 is
    # the number of dyads in an 7-node undirected network).
    # Here's a check of that fact:
    as.vector(a$weights - choose(21, t(a$statmat)))
    # Simple ergm.exact outpuf for this network.
    # We know that the loglikelihood for my empty 7-node network
    # should simply be -21*log(1+exp(eta)), so we may check that
    # the following two values agree:
    -21*log(1+exp(.1234))
    ergm.exact(.1234, mynw~edges, statmat=a$statmat, weights=a$weights)
```

ergm.getnetwork Acquire and verify the network from the LHS of an ergm formula and verify that it is a valid network.

## Description

The function function ensures that the network in a given formula is valid; if so, the network is returned; if not, execution is halted with warnings.

## Usage

ergm.getnetwork(formula, loopswarning = TRUE)

## Arguments

formula a two-sided formula whose LHS is a network, an object that can be coerced to a network, or an expression that evaluates to one.
loopswarning whether warnings about loops should be printed (TRUE or FALSE); defaults to TRUE.

## Value

A network object constructed by evaluating the LHS of the model formula in the formula's environment.

## Description

Gives the network a series of proposals it can't refuse. Returns the statistics of the network, and, optionally, the final network.

## Usage

ergm.godfather (
formula,
changes $=$ NULL,
response $=$ NULL,
end.network = FALSE,
stats.start = FALSE,
changes.only = FALSE,
verbose = FALSE,
control = control.ergm.godfather()
)

## Arguments

formula An ergm-style formula, with a network on its LHS.
changes Either a matrix with three columns: tail, head, and new value, describing the changes to be made; or a list of such matrices to apply these changes in a sequence. For binary network models, the third column may be omitted. In that case, the changes are treated as toggles. Note that if a list is passed, it must either be all of changes or all of toggles.
response Either a character string, a formula, or NULL (the default), to specify the response attributes and whether the ERGM is binary or valued. Interpreted as follows:

NULL Model simple presence or absence, via a binary ERGM.
character string The name of the edge attribute whose value is to be modeled. Type of ERGM will be determined by whether the attribute is logical (TRUE/FALSE) for binary or numeric for valued.
a formula must be of the form NAME~EXPR|TYPE (with | being literal). EXPR is evaluated in the formula's environment with the network's edge attributes accessible as variables. The optional NAME specifies the name of the edge attribute into which the results should be stored, with the default being a concise version of EXPR. Normally, the type of ERGM is determined by whether the result of evaluating EXPR is logical or numeric, but the optional TYPE can be used to override by specifying a scalar of the type involved (e.g., TRUE for binary and 1 for valued).
end.network Whether to return a network that results. Defaults to FALSE.
stats.start Whether to return the network statistics at start (before any changes are applied) as the first row of the statistics matrix. Defaults to FALSE, to produce output similar to that of simulate for ERGMs when output="stats", where initial network's statistics are not returned.
changes.only Whether to return network statistics or only their changes relative to the initial network.
verbose A logical or an integer to control the amount of progress and diagnostic information to be printed. FALSE/0 produces minimal output, wit higher values producing more detail. Note that very high values (5+) may significantly slow down processing.
control A list of control parameters for algorithm tuning, typically constructed with control.ergm.godfather(). Its documentation gives the the list of recognized control parameters and their meaning. The more generic utility snctrl() (StatNet ConTRoL) also provides argument completion for the available control functions and limited argument name checking.

## Value

If end. network==FALSE (the default), an mcmc object with the requested network statistics associed with the network series produced by applying the specified changes. Its mcmc attributes encode the timing information: so start (out) gives the time point associated with the first row returned, and end (out) out the last. The "thinning interval" is always 1.
If end.network==TRUE, return a network object, representing the final network, with a matrix of statistics described in the previous paragraph attached to it as an attr-style attribute "stats".

                                cbind(3,5),
                                cbind(3,5),
                                cbind(1:2,2:3)),
        stats.start=TRUE)
```

ergmConstraint Sample Space Constraints for Exponential-Family Random Graph
Models

## Description

This page describes how to specify the constraints on the network sample space (the set of possible networks $Y$, the set of networks $y$ for which $h(y)>0)$ and sometimes the baseline weights $h(y)$ to functions in the ergm package. It also provides an indexed list of the constraints visible to the ergm's API.

## Specifying constraints

In an exponential-family random graph model (ERGM), the probability or density of a given network, $y \in Y$, on a set of nodes is

$$
h(y) \exp [\eta(\theta) \cdot g(y)] / \kappa(\theta)
$$

where $h(y)$ is the reference distribution (particularly for valued network models), $g(y)$ is a vector of network statistics for $y, \eta(\theta)$ is a natural parameter vector of the same length (with $\eta(\theta) \equiv \theta$ for most terms), • is the dot product, and $\kappa(\theta)$ is the normalizing constant for the distribution. A complete ERGM specification requires a list of network statistics $g(y)$ and (if applicable) their $\eta(\theta)$ mappings provided by a formula of ergmTerms; and, optionally, sample space $\mathcal{Y}$ and reference distribution $h(y)$ information provided by ergmConstraints and, for valued ERGMs, by ergmReferences. Constraints typically affect $Y$, or, equivalently, set $h(y)=0$ for some $y$, but some ("soft" constraints) set $h(y)$ to values other than 0 and 1 .

A constraints formula is a one- or two-sided formula whose left-hand side is an optional direct selection of the InitErgmProposal function and whose right-hand side is a series of one or more terms separated by " + " and " - " operators, specifying the constraint.
The sample space (over and above the reference distribution) is determined by iterating over the constraints terms from left to right, each term updating it as follows:

- If the constraint introduces complex dependence structure (e.g., constrains degree or number of edges in the network), then this constraint always restricts the sample space. It may only have a " + " sign.
- If the constraint only restricts the set of dyads that may vary in the sample space (e.g., blockdiagonal structure or fixing specific dyads at specific values) and has a " + " sign, the set of dyads that may vary is restricted to those that may vary according to this constraint and all the constraints to date.
- If the constraint only restricts the set of dyads that may vary in the sample space but has a "-" sign, the set of dyads that may vary is expanded to those that may vary according to this constraint or all the constraints up to date.

For example, a constraints formula $\sim a-b+c-d$ with all constraints dyadic will allow dyads permitted by either a or b but only if they are also permitted by $c$; as well as all dyads permitted by $d$. If $A, B$, $C$, and $D$ were logical matrices, the matrix of variable dyads would be equal to $((A \mid B) \& C) \mid D$.
Terms with a positive sign can be viewed as "adding" a constraint while those with a negative sign can be viewed as "relaxing" a constraint.
The constraints formula can also contain a .. If present, \%ergmlhs\% attributes constraints and constraints.obs will be substituted in its place.

## Constraints visible to the package

Term Package Description Concepts

| ```Dyads(fix=NULL, vary=NULL)``` | ergm | Constrain fixed or varying dyad-independent terms | directed <br> dyad- <br> independent <br> operator <br> undi- <br> rected |

```
ergmHint MCMC Hints for Exponential-Family Random Graph Models
```

## Description

This page describes how to provide to the ergm's MCMC algorithms information about the sample space.

## "Hints" for MCMC

In an exponential-family random graph model (ERGM), the probability or density of a given network, $y \in Y$, on a set of nodes is

$$
h(y) \exp [\eta(\theta) \cdot g(y)] / \kappa(\theta),
$$

where $h(y)$ is the reference distribution (particularly for valued network models), $g(y)$ is a vector of network statistics for $y, \eta(\theta)$ is a natural parameter vector of the same length (with $\eta(\theta) \equiv \theta$ for most terms), • is the dot product, and $\kappa(\theta)$ is the normalizing constant for the distribution. A complete ERGM specification requires a list of network statistics $g(y)$ and (if applicable) their $\eta(\theta)$ mappings provided by a formula of ergmTerms; and, optionally, sample space $\mathcal{Y}$ and reference distribution $h(y)$ information provided by ergmConstraints and, for valued ERGMs, by ergmReferences.

It is often the case that there is additional information available about the distribution of networks being modelled. For example, you may be aware that the network is sparse or that there are strata among the dyads. "Hints", typically passed on the right-hand side of MCMC.prop and obs.MCMC.prop arguments to control.ergm(), control.simulate.ergm(), and others, allow this information to be provided. By default, hint sparse is in effect.
Unlike constraints, model terms, and reference distributions, "hints" do not affect the specification of the model. That is, regardless of what "hints" may or may not be in effect, the sample space and the probabilities within it are the same. However, "hints" may affect the MCMC proposal distribution used by the samplers.

Note that not all proposals support all "hints": and if the most suitable proposal available cannot incorporate a particular "hint", a warning message will be printed.
"Hints" use the same underlying API as constraints, and, if present, \%ergmlhs\% attributes constraints and constraints.obs will be substituted in its place.

## Hints available to the package

The following hints are known to ergm at this time:

| Term | Package | Description | Concepts |
| :--- | :--- | :--- | :--- |
| sparse | ergm | Sparse network | dyad- <br> independent |
| strat $($ attr=NULL, <br> pmat $=$ NULL,, <br> empirical=FALSE $)$ | ergm | Stratified dyads | dyad- <br> independent |

ergmMPLE
ERGM Predictors and response for logistic regression calculation of
$M P L E$

## Description

Return the predictor matrix, response vector, and vector of weights that can be used to calculate the MPLE for an ERGM.

## Usage

ergmMPLE (
formula,
constraints $=\sim$.,
obs.constraints $=\sim-o b s e r v e d$,
output = c("matrix", "array", "dyadlist", "fit"),
expand.bipartite = FALSE,
control = control.ergm(),
verbose $=$ FALSE,
....,
basis = ergm.getnetwork(formula)
)

## Arguments

formula, constraints, obs.constraints
An ERGM formula and (optional) constraint specification formulas. See ergm.
output Character, partially matched. See Value.
expand.bipartite
Logical. Specifies whether the output matrices (or array slices) representing dyads for bipartite networks are represented as rectangular matrices with first mode vertices in rows and second mode in columns, or as square matrices with dimension equalling the total number of vertices, containing with structural NAs or 0s within each mode.
control A list of control parameters for algorithm tuning, typically constructed with control.ergm (). Its documentation gives the the list of recognized control parameters and their meaning. The more generic utility snctrl() (StatNet ConTRoL) also provides argument completion for the available control functions and limited argument name checking.

| verbose | A logical or an integer to control the amount of progress and diagnostic in- <br> formation to be printed. FALSE/0 produces minimal output, wit higher values <br> producing more detail. Note that very high values (5+) may significantly slow <br> down processing. |
| :--- | :--- |
| $\ldots$ | Additional arguments, to be passed to lower-level functions. |
| basis | a value (usually a network) to override the LHS of the formula. |

## Details

The MPLE for an ERGM is calculated by first finding the matrix of change statistics. Each row of this matrix is associated with a particular pair (ordered or unordered, depending on whether the network is directed or undirected) of nodes, and the row equals the change in the vector of network statistics (as defined in formula) when that pair is toggled from a 0 (no edge) to a 1 (edge), holding all the rest of the network fixed. The MPLE results if we perform a logistic regression in which the predictor matrix is the matrix of change statistics and the response vector is the observed network (i.e., each entry is either 0 or 1 , depending on whether the corresponding edge exists or not).

Using output="matrix", note that the result of the fit may be obtained from the glm function, as shown in the examples below.

## Value

If output=="matrix" (the default), then only the response, predictor, and weights are returned; thus, the MPLE may be found by hand or the vector of change statistics may be used in some other way. To save space, the algorithm will automatically search for any duplicated rows in the predictor matrix (and corresponding response values). ergmMPLE function will return a list with three elements, response, predictor, and weights, respectively the response vector, the predictor matrix, and a vector of weights, which are really counts that tell how many times each corresponding response, predictor pair is repeated.
If output=="dyadlist", as "matrix", but rather than coalescing the duplicated rows, every relation in the network that is not fixed and is observed will have its own row in predictor and element in response and weights, and predictor matrix will have two additional rows at the start, tail and head, indicating to which dyad the row and the corresponding elements pertain.
If output=="array", a list with similarly named three elements is returned, but response is formatted into a sociomatrix; predictor is a 3-dimensional array of with cell predictor [t,h,k] containing the change score of term $k$ for dyad ( $t, h$ ); and weights is also formatted into a sociomatrix, with an element being 1 if it is to be added into the pseudolikelihood and 0 if it is not.

In particular, for a unipartite network, cells corresponding to self-loops, i.e., predictor $[i, i, k]$ will be NA and weights[i,i] will be 0 ; and for a unipartite undirected network, lower triangle of each predictor $[,, k]$ matrix will be set to NA, with the lower triangle of weights being set to 0 .
To all of the above output types, attr(., "etamap") is attached containing the mapping and offset information.
If output=="fit", then ergmMPLE simply calls the ergm function with the estimate="MPLE" option set, returning an object of class ergm that gives the fitted pseudolikelihood model.

## Examples

```
data(faux.mesa.high)
formula <- faux.mesa.high ~ edges + nodematch("Sex") + nodefactor("Grade")
mplesetup <- ergmMPLE(formula)
# Obtain MPLE coefficients "by hand":
coef(glm(mplesetup$response ~ . - 1, data = data.frame(mplesetup$predictor),
    weights = mplesetup$weights, family="binomial"))
# Check that the coefficients agree with the output of the ergm function:
coef(ergmMPLE(formula, output="fit"))
# We can also format the predictor matrix into an array:
mplearray <- ergmMPLE(formula, output="array")
# The resulting matrices are big, so only print the first 8 actors:
mplearray$response[1:8,1:8]
mplearray$predictor[1:8,1:8,]
mplearray$weights[1:8,1:8]
if(require(tergm)){
# Constraints are handled:
faux.mesa.high%v%"block" <- seq_len(network.size(faux.mesa.high)) %/% 4
mplearray <- ergmMPLE(faux.mesa.high~edges, constraints=~blockdiag("block"), output="array")
mplearray$response[1:8,1:8]
mplearray$predictor[1:8,1:8,]
mplearray$weights[1:8,1:8]
# Or, a dyad list:
faux.mesa.high%v%"block" <- seq_len(network.size(faux.mesa.high)) %/% 4
mplearray <- ergmMPLE(faux.mesa.high~edges, constraints=~blockdiag("block"), output="dyadlist")
mplearray$response[1:8]
mplearray$predictor[1:8,]
mplearray$weights[1:8]
}
# Curved terms produce predictors on the canonical scale:
formula2 <- faux.mesa.high ~ gwesp
mplearray <- ergmMPLE(formula2, output="array")
# The resulting matrices are big, so only print the first 5 actors:
mplearray$response[1:5,1:5]
mplearray$predictor[1:5,1:5,1:3]
mplearray$weights[1:5,1:5]
```

## Description

ergm uses a Metropolis-Hastings (MH) algorithm to control the behavior of the Markov Chain Monte Carlo (MCMC) for sampling networks. The MCMC chain is intended to step around the
sample space of possible networks, selecting a network at regular intervals to evaluate the statistics in the model. For each MCMC step, $n$ ( $n=1$ in the simple case) toggles are proposed to change the dyad(s) to the opposite value. The probability of accepting the proposed change is determined by the MH acceptance ratio. The role of the different MH methods implemented in ergm is to vary how the sets of dyads are selected for toggle proposals. This is used in some cases to improve the performance (speed and mixing) of the algorithm, and in other cases to constrain the sample space.

## Description

This page describes how to specify the reference measures (baseline distributions) (the set of possible networks $Y$ and the baseline weights $h(y)$ to functions in the ergm package. It also provides an indexed list of the references visible to the ergm's API.

## Specifying reference measures

In an exponential-family random graph model (ERGM), the probability or density of a given network, $y \in Y$, on a set of nodes is

$$
h(y) \exp [\eta(\theta) \cdot g(y)] / \kappa(\theta),
$$

where $h(y)$ is the reference distribution (particularly for valued network models), $g(y)$ is a vector of network statistics for $y, \eta(\theta)$ is a natural parameter vector of the same length (with $\eta(\theta) \equiv \theta$ for most terms), • is the dot product, and $\kappa(\theta)$ is the normalizing constant for the distribution. A complete ERGM specification requires a list of network statistics $g(y)$ and (if applicable) their $\eta(\theta)$ mappings provided by a formula of ergmTerms; and, optionally, sample space $\mathcal{Y}$ and reference distribution $h(y)$ information provided by ergmConstraints and, for valued ERGMs, by ergmReferences.

The reference measure $(Y, h(y))$ is specified on the right-hand side of a one-sided formula passed typically as the reference argument.
ergmReference

## See Also

ergmTerm Terms used in Exponential Family Random Graph Models

## Description

This page explains how to specify the network statistics $g(y)$ to functions in the ergm package and packages that extend it. It also provides an indexed list of the possible terms (and hence network statistics) visible to the ergm API. Terms can also be searched via search. ergmTerms.

## Specifying models

In an exponential-family random graph model (ERGM), the probability or density of a given network, $y \in Y$, on a set of nodes is

$$
h(y) \exp [\eta(\theta) \cdot g(y)] / \kappa(\theta)
$$

where $h(y)$ is the reference distribution (particularly for valued network models), $g(y)$ is a vector of network statistics for $y, \eta(\theta)$ is a natural parameter vector of the same length (with $\eta(\theta) \equiv \theta$ for most terms), • is the dot product, and $\kappa(\theta)$ is the normalizing constant for the distribution. A complete ERGM specification requires a list of network statistics $g(y)$ and (if applicable) their $\eta(\theta)$ mappings provided by a formula of ergmTerms; and, optionally, sample space $\mathcal{Y}$ and reference distribution $h(y)$ information provided by ergmConstraints and, for valued ERGMs, by ergmReferences.
Network statistics $g(y)$ and mappings $\eta(\theta)$ are specified by a formula object, of the form y $\sim$ <term $1>+<$ term $2>\ldots$, where $y$ is a network object or a matrix that can be coerced to a network object, and <term 1>, <term 2>, etc, are each terms chosen from the list given below. To create a network object in, use the network function, then add nodal attributes to it using the \%v\% operator if necessary.

## Operator terms:

Operator terms like B and F take formulas with other ergm terms as their arguments and transform them by modifying their inputs (e.g., the network they evaluate) and/or their outputs.
By convention, their names are capitalized and CamelCased.

## Interactions:

For binary ERGMs, interactions between ergm terms can be specified in a manner similar to 1 m and others, as using the : and * operators. However, they must be interpreted carefully, especially for dyad-dependent terms. (Interactions involving curved terms are not supported at this time.)
Generally, if term a has $p_{a}$ statistics and b has $p_{b}, \mathrm{a}: \mathrm{b}$ will add $p_{a} \times p_{b}$ statistics to the model, corresponding to each element of $g_{a}(y)$ interacted with each element of $g_{b}(y)$.
The interaction is defined as follows. Dyad-independent terms can be expressed in the general form $g(y ; x)=\sum_{i, j} x_{i, j} y_{i, j}$ for some edge covariate matrix $x$,

$$
g_{a: b}(y)=\sum_{i, j} x_{a, i, j} x_{b, i, j} y_{i, j}
$$

In other words, rather than being a product of their sufficient statistics $\left(g_{a}(y) g_{b}(y)\right)$, it is a dyadwise product of their dyad-level effects.

This means that an interaction between two dyad-independent terms can be interpreted the same way as it would be in the corresponding logistic regression for each potential edge. However, for undirected networks in particular, this may lead to somewhat counterintuitive results. For example, given two nodal covariates "a" and "b" (whose values for node $i$ are denoted $a_{i}$ and $b_{i}$, respectively), nodecov(" a ") adds one statistic of the form $\sum_{i, j}\left(a_{i}+a_{j}\right) y_{i, j}$ and analogously for nodecov("b"), so nodecov("a"): nodecov("b") produces

$$
\sum_{i, j}\left(a_{i}+a_{j}\right)\left(b_{i}+b_{j}\right) y_{i, j}
$$

## Binary and valued ERGM terms:

ergm functions such as ergm and simulate (for ERGMs) may operate in two modes: binary and weighted/valued, with the latter activated by passing a non-NULL value as the response argument, giving the edge attribute name to be modeled/simulated.

## Generalizations of binary terms:

Binary ERGM statistics cannot be used directly in valued mode and vice versa. However, a substantial number of binary ERGM statistics - particularly the ones with dyadic independence - have simple generalizations to valued ERGMs, and have been adapted in ergm. They have the same form as their binary ERGM counterparts, with an additional argument: form, which, at this time, has two possible values: "sum" (the default) and "nonzero". The former creates a statistic of the form $\sum_{i, j} x_{i, j} y_{i, j}$, where $y_{i, j}$ is the value of dyad $(i, j)$ and $x_{i, j}$ is the term's covariate associated with it. The latter computes the binary version, with the edge considered to be present if its value is not 0 . Valued version of some binary ERGM terms have an argument threshold, which sets the value above which a dyad is conidered to have a tie. (Value less than or equal to threshold is considered a nontie.)
The $B()$ operator term documented below can be used to pass other binary terms to valued models, and is more flexible, at the cost of being somewhat slower.

## Nodal attribute levels and indices:

Terms taking a categorical nodal covariate also take the levels argument. (There are analogous b1levels and b2levels arguments for some terms that apply to bipartite networks, and the levels2 argument for mixing terms.) The levels argument can be used to control the set and the ordering of attribute levels.
Terms that allow the selection of nodes do so with the nodes argument, which is interpreted in the same way as the levels argument, where the categories are the relevant nodal indices themselves.
Both levels and nodes use the new level selection UI. (See Specifying Vertex attributes and Levels (?
nodal_attributes) for details.)

## Legacy arguments:

The legacy base and keep arguments are deprecated as of version 3.10, and replaced by the levels UI. The levels argument provides consistent and flexible mechanisms for specifying which attribute levels to exclude (previously handled by base) and include (previously handled by keep). If levels or nodes argument is given, then base and keep arguments are ignored. The legacy arguments will most likely be removed in a future version.
Note that this exact behavior is new in version 3.10, and it differs slightly from older versions: previously if both levels and base/keep were given, levels argument was applied first and then applied the base/keep argument. Since version 3.10, base/keep would be ignored, even if old term behavior is invoked (as described in the next section).

## Term versioning:

When a term's behavior has changed from prior version, it is often possible to invoke the old behavior by setting and/or passing a version term option, giving the verison (constructed by as. package_version) desired.

## Custom ergm terms:

Users and other packages may build custom terms, and package ergm.userterms (https:// github.com/statnet/ergm. userterms) provides tools for implementing them.
The current recommendation for any package implementing additional terms is to document the term with Roxygen comments and a name in the form termName-ergmTerm. This ensures that help("ergmTerm") will list ERGM terms available from all loaded packages.

Terms included in the ergm package
As noted above, a cross-referenced HTML version of the term documentation is also available via vignette('ergm-term-crossRef') and terms can also be searched via search.ergmTerms.

Term index (operator):

| Term | Package | Description | Concepts |
| :--- | :--- | :--- | :--- |
| B(formula, form) (val) | ergm | Wrap binary terms for use in valued models | operator |

| Curve(formula, params, map, gradient, minpar, maxpar, cov) (bin) Parametrise(formula, params, map, gradient, minpar, maxpar, cov) (bin) Parametrize(formula, params, map, gradient, minpar, maxpar, cov) (bin) Curve(formula, params, map, gradient, minpar, maxpar, cov) (val) <br> Parametrise(formula, params, map, gradient, minpar, maxpar, cov) (val) Parametrize(formula, params, map, gradient, minpar, maxpar, cov) (val) | ergm | Impose a curved structure on term parameters | operator |
| :---: | :---: | :---: | :---: |
| Exp(formula) (bin) Exp(formula) (val) | ergm | Exponentiate a network's statistic | operator |
| $\begin{aligned} & \text { F(formula, filter) (bin) } \\ & \hline \text { Label(formula, label, } \\ & \text { pos) (bin) } \\ & \text { Label(formula, label, } \\ & \text { pos) (val) } \end{aligned}$ | ergm ergm | Filtering on arbitrary one-term model Modify terms' coefficient names | operator |
| Log(formula, log0) (bin) Log(formula, log0) (val) | ergm | Take a natural logarithm of a network's statistic | operator |
| NodematchFilter(formula, attrname) (bin) | ergm | Filtering on nodematch | operator |
| Offset(formula, coef, which) (bin) | ergm | Terms with fixed coefficients | operator |
| Prod(formulas, label) (bin) <br> Prod(formulas, label) (val) | ergm | A product (or an arbitrary power combination) of one or more formulas | operator |
| S(formula, attrs) (bin) | ergm | Evaluation on an induced subgraph | operator |
| $\begin{aligned} & \text { Sum(formulas, label) (bin) } \\ & \text { Sum(formulas, label) (val) } \end{aligned}$ | ergm | A sum (or an arbitrary linear combination) of one or more formulas | operator |
| Symmetrize(formula, rule) (bin) | ergm | Evaluation on symmetrized (undirected) network | directed operator |

## Frequently-used terms:

    ergm_MCMC_sample Internal Function to Sample Networks and Network Statistics
    
## Description

This is an internal function, not normally called directly by the user. The ergm_MCMC_sample function samples networks and network statistics using an MCMC algorithm via MCMC_wrapper and is capable of running in multiple threads using ergm_MCMC_slave.
The ergm_MCMC_slave function calls the actual $C$ routine and does minimal preprocessing.

## Usage

ergm_MCMC_sample( state, control, theta $=$ NULL, verbose = FALSE,
...,
eta $=$ ergm.eta(theta, (if (is.ergm_state(state)) as.ergm_model(state) else as.ergm_model(state[[1]]))\$etamap)
)
ergm_MCMC_slave(
state,
eta,
control,
verbose,
...,
burnin = NULL,
samplesize = NULL,
interval = NULL
)

## Arguments

$$
\begin{array}{ll}
\text { state } & \begin{array}{l}
\text { an ergm_state representing the sampler state, containing information about } \\
\text { the network, the model, the proposal, and (optionally) initial statistics, or a list } \\
\text { thereof. }
\end{array} \\
\text { control } & \begin{array}{l}
\text { A list of control parameters for algorithm tuning, typically constructed with } \\
\text { control.ergm(), control. simulate.ergm(), etc., which have different de- } \\
\text { faults. Their documentation gives the the list of recognized control parameters } \\
\text { and their meaning. The more generic utility snctrl() (StatNet ConTRoL) also } \\
\text { provides argument completion for the available control functions and limited } \\
\text { argument name checking. } \\
\text { the (possibly curved) parameters of the model. }
\end{array} \\
\text { theta } & \begin{array}{l}
\text { A logical or an integer to control the amount of progress and diagnostic in- } \\
\text { formation to be printed. FALSE/0 produces minimal output, wit higher values } \\
\text { producing more detail. Note that very high values (5+) may significantly slow } \\
\text { down processing. }
\end{array} \\
\ldots & \begin{array}{l}
\text { additional arugments. }
\end{array} \\
\text { eta natural parameters of the model; by default constructed from theta. } \\
\text { etarnin, samplesize, interval }
\end{array} \quad \begin{aligned}
& \text { MCMC paramters that can be used to temporarily override those in the control } \\
& \text { bist. }
\end{aligned}
$$

## Value

ergm_MCMC_sample returns a list containing:
stats an memc.list with sampled statistics.
networks a list of final sampled networks, one for each thread.
status status code, propagated from ergm_MCMC_slave().
final.interval adaptively determined MCMC interval.
sampnetworks If control\$MCMC. save_networks is set and is TRUE, a list of lists of ergm_states corresponding to the sampled networks.
ergm_MCMC_slave returns the MCMC sample as a list of the following:
s the matrix of statistics.
state an ergm_state object for the new network.
status success or failure code: 0 is success, 1 for too many edges, and 2 for a MetropolisHastings proposal failing, -1 for ergm_model or ergm_proposal not passed and missing from the cache.

Note
ergm_MCMC_sample and ergm_MCMC_slave replace ergm.getMCMCsample and ergm.mcmcslave respectively. They differ slightly in their argument names and in their return formats. For example, ergm_MCMC_sample expects ergm_state rather than network/model/proposal, and theta or eta rather than eta0; and it does not return statsmatrix or newnetwork elements. Rather, if parallel
processing is not in effect, stats is an mcmc.list with one chain and networks is a list with one element.
Note that unless stats is a part of the ergm_state, the returned stats will be relative to the original network, i.e., the calling function must shift the statistics if required.

At this time, repeated calls to ergm_MCMC_sample will not produce the same sequence of networks as a single long call, even with the same starting seeds. This is because the network sampling algorithms rely on the internal state of the network representation in C, which may not be reconstructed exactly the same way when "resuming". This behaviour may change in the future.

## Examples

```
# This example illustrates constructing "ingredients" for calling
# ergm_MCMC_sample() from calls to simulate.ergm(). One can also
# construct an ergm_state object directly from ergm_model(),
# ergm_proposal(), etc., but the approach shown here is likely to
# be the least error-prone and the most robust to future API
# changes.
#
# The regular simulate() call hierarchy is
#
# simulate_formula.network(formula) ->
# simulate.ergm_model(ergm_model) ->
# simulate.ergm_state_full(ergm_state)
#
# They take an argument, return.args=, that will interrupt the call
# and have it return its arguments. We can use it to obtain
# low-level inputs robustly.
data(florentine)
control <- control.simulate(MCMC.burnin = 2, MCMC.interval = 1)
# FYI: Obtain input for simulate.ergm_model():
sim.mod <- simulate(flomarriage~absdiff("wealth"), constraints=~edges,
    coef = NULL, nsim=3, control=control,
    return.args="ergm_model")
names(sim.mod)
str(sim.mod$object,1) # ergm_model
# Obtain input for simulate.ergm_state_full():
sim.state <- simulate(flomarriage~absdiff("wealth"), constraints=~edges,
    coef = NULL, nsim=3, control=control,
    return.args="ergm_state")
names(sim.state)
str(sim.state$object, 1) # ergm_state
# This control parameter would be set by nsim in the regular
# simulate() call:
control$MCMC.samplesize <- 3
# Capture intermediate networks; can also be left NULL for just the
# statistics:
```

```
control$MCMC.save_networks <- TRUE
# Simulate starting from this state:
out <- ergm_MCMC_sample(sim.state$object, control, theta = -1, verbose=6)
names(out)
out$stats # Sampled statistics
str(out$networks, 1) # Updated ergm_state (one per thread)
# List (an element per thread) of lists of captured ergm_states,
# one for each sampled network:
str(out$sampnetworks, 2)
lapply(out$sampnetworks[[1]], as.network) # Converted to networks.
# One more, picking up where the previous sampler left off, but see Note:
control$MCMC.samplesize <- 1
str(ergm_MCMC_sample(out$networks, control, theta = -1, verbose=6), 2)
```

ergm_plot.mcmc.list Plot MCMC list using lattice package graphics

## Description

Plot MCMC list using lattice package graphics

## Usage

ergm_plot.mcmc.list(x, main = NULL, vars.per.page = 3, ...)

## Arguments

x an mcmc. list object containing the mcmc diagnostic samples.

## main

 character, main plot heading title.vars.per. page Number of rows (one variable per row) per plotting page. Ignored if latticeExtra package is not installed.
$\ldots \quad$ additional arguments, currently unused.

Note
This is not a method at this time.
ergm_state_cache A rudimentary cache for large objects

## Description

This cache is intended to store large, infrequently changing data structures such as ergm_models and ergm_proposals on worker nodes.

## Usage

```
    ergm_state_cache(
        comm = c("pass", "all", "clear", "insert", "get", "check", "list"),
        hash,
        object
    )
```

## Arguments

comm
hash a character string, typically a digest() of the object.
object
a character string giving the desired function; see the default argument above for permitted values and Details for meanings; partial matching is supported.
, the object to be stored.

Supported tasks are, respectively, to do nothing (the default), return all entries (mainly useful for testing), clear the cache, insert into cache, retrieve an object by hash, check if a hash is present, or list hashes defined.
Deleting an entry can be accomplished by inserting a NULL for that hash.
Cache is limited to a hard-coded size (currently 4). This should accommodate an ergm_model and an ergm_proposal for unconstrained and constrained MCMC. When additional objects are stored, the oldest object is purged and garbagecollected.

## Note

If called via, say, clusterMap(cl, ergm_state_cache, ...) the function will not accomplish anything. This is because parallel package will serialise the ergm_state_cache() function object, send it to the remote node, evaluate it there, and fetch the return value. This will leave the environment of the worker's ergm_state_cache() unchanged. To actually evaluate it on the worker nodes, it is recommended to wrap it in an empty function whose environment is set to globalenv (). See Examples below.

## Examples

```
## Not run:
# Wrap ergm_state_cache() and call it explicitly from ergm:
call_ergm_state_cache <- function(...) ergm::ergm_state_cache(...)
# Reset the function's environment so that it does not get sent to
```

```
# worker nodes (who have their own instance of ergm namespace
# loaded).
environment(call_ergm_state_cache) <- globalenv()
# Now, call the the wrapper function, with ... below replaced by
# lists of desired arguments.
clusterMap(cl, call_ergm_state_cache, ...)
## End(Not run)
```

ergm_symmetrize Return a symmetrized version of a binary network

## Description

Return a symmetrized version of a binary network

## Usage

```
ergm_symmetrize(x, rule = c("weak", "strong", "upper", "lower"), ...)
## Default S3 method:
ergm_symmetrize(x, rule = c("weak", "strong", "upper", "lower"), ...)
## S3 method for class 'network'
ergm_symmetrize(x, rule = c("weak", "strong", "upper", "lower"), ...)
```

## Arguments

$x \quad$ an object representing a network.
rule a string specifying how the network is to be symmetrized; see sna: :symmetrize() for details; for the network method, it can also be a function or a list; see Details.
... additional arguments to sna: : symmetrize().

## Details

The network method requires more flexibility, in order to specify how the edge attributes are handled. Therefore, rule can be one of the following types:
a character vector The string is interpreted as in sna: : symmetrize(). For edge attributes, "weak" takes the maximum value and "strong" takes the minimum value" for ordered attributes, and drops the unordered.
a function The function is evaluated on a data.frame constructed by joining (via merge()) the edge tibble with all attributes and NA indicators with itself reversing tail and head columns, and appending original columns with ". th" and the reversed columns with ".ht". It is then evaluated for each attribute in turn, given two arguments: the data frame and the name of the attribute.
a list The list must have exactly one unnamed element, and the remaining elements must be named with the names of edge attributes. The elements of the list are interpreted as above, allowing each edge attribute to be handled differently. Unnamed arguments are dropped.

## Methods (by class)

- default: The default method, passing the input on to sna: :symmetrize().
- network: A method for network objects, which preserves network and vertex attributes, and handles edge attributes.

## Note

This was originally exported as a generic to overwrite sna: :symmetrize(). By developer's request, it has been renamed; eventually, sna or network packages will export the generic instead.

## Examples

```
data(sampson)
samplike[1,2] <- NA
samplike[4.1] <- NA
sm <- as.matrix(samplike)
tst <- function(x,y){
    mapply(identical, x, y)
}
stopifnot(all(tst(as.logical(as.matrix(ergm_symmetrize(samplike, "weak"))), sm | t(sm))),
        all(tst(as.logical(as.matrix(ergm_symmetrize(samplike, "strong"))), sm & t(sm))),
            all(tst(c(as.matrix(ergm_symmetrize(samplike, "upper"))),
                    sm[cbind(c(pmin(row(sm),col(sm))),c(pmax(row(sm),col(sm))))])),
            all(tst(c(as.matrix(ergm_symmetrize(samplike, "lower"))),
                    sm[cbind(c(pmax(row(sm),col(sm))),c(pmin(row(sm),col(sm))))])))
```

esp-ergmTerm Edgewise shared partners

## Description

This is just like the dsp term, except this term adds one network statistic to the model for each element in d where the $i$ th such statistic equals the number of edges (rather than dyads) in the network with exactly $\mathrm{d}[\mathrm{i}]$ shared partners. This term can be used with directed and undirected networks.

## Usage

\# binary: esp(d)

## Arguments

d
a vector of distinct integers

## Note

For directed networks, only outgoing two-path ("OTP") shared partners are counted. In other words, for a (directed) edge $i->j$ in a directed graph, the number of shared partners counted by esp is the number of nodes $k$ that have edges $i->k->j$. (These may also be called homogeneous shared partners.) To count other types of shared partners instead, see desp.

## See Also

ergmTerm for index of model terms currently visible to the package.
Exp-ergmTerm Exponentiate a network's statistic

## Description

Evaluate the terms specified in formula and exponentiates them with base $e$.

## Usage

\# binary: Exp(formula)
\# valued: Exp(formula)

## Arguments

formula a one-sided ergm()-style formula with the terms to be evaluated

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

Evaluates the given formula on a network constructed by taking $y$ and removing any edges for which $f_{i, j}\left(y_{i, j}\right)=0$.

## Usage

\# binary: F(formula, filter)

## Arguments

formula a one-sided ergm()-style formula with the terms to be evaluated
filter must contain one binary ergm term, with the following properties:

- dyadic independence;
- dyadwise contribution of 0 for a 0 -valued dyad.

Formally, this means that it is expressable as

$$
g(y)=\sum_{i, j} f_{i, j}\left(y_{i, j}\right)
$$

where for all $i, j$, and $y, f_{i, j}\left(y_{i, j}\right)$ for which $f_{i, j}(0)=0$. For convenience, the term in specified can be a part of a simple logical or comparison operation: (e.g., $\sim!$ nodematch("A") or $\sim$ abs (" X " $)>3$ ), which filters on $f_{i, j}\left(y_{i, j}\right) \bigcirc 0$ instead.

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

This data set represents a simulation of a directed in-school friendship network. The network is named faux.desert.high.

## Usage

data(faux.desert.high)

## Format

faux. desert.high is a network object with 107 vertices (students, in this case) and 439 directed edges (friendship nominations). To obtain additional summary information about it, type summary (faux. desert.high).
The vertex attributes are Grade, Sex, and Race. The Grade attribute has values 7 through 12, indicating each student's grade in school. The Race attribute is based on the answers to two questions, one on Hispanic identity and one on race, and takes six possible values: White (non-Hisp.), Black (non-Hisp.), Hispanic, Asian (non-Hisp.), Native American, and Other (non-Hisp.)

## Licenses and Citation

If the source of the data set does not specified otherwise, this data set is protected by the Creative Commons License https://creativecommons.org/licenses/by-nc-nd/2.5/.
When publishing results obtained using this data set, the original authors (Resnick et al, 1997) should be cited. In addition this package should be cited as:
Mark S. Handcock, David R. Hunter, Carter T. Butts, Steven M. Goodreau, and Martina Morris. 2003 statnet: Software tools for the Statistical Modeling of Network Data https://statnet.org.

## Source

The data set is simulation based upon an ergm model fit to data from one school community from the AddHealth Study, Wave I (Resnick et al., 1997). It was constructed as follows:
The school in question (a single school with 7th through 12th grades) was selected from the Add Health "structure files." Documentation on these files can be found here: https://addhealth. cpc.unc.edu/documentation/codebooks/.
The stucture file contains directed out-ties representing each instance of a student who named another student as a friend. Students could nominate up to 5 male and 5 female friends. Note that registered students who did not take the AddHealth survey or who were not listed by name on the schools' student roster are not included in the stucture files. In addition, we removed any students with missing values for race, grade or sex.
The following ergm model was fit to the original data (with code updated for modern syntax):

```
desert.fit <- ergm(original.net ~ edges + mutual +
absdiff("grade") + nodefactor("race", base=5) + nodefactor("grade", base=3)
+ nodefactor("sex") + nodematch("race", diff = TRUE) + nodematch("grade",
diff = TRUE) + nodematch("sex", diff = FALSE) + idegree(0:1) + odegree(0:1)
+ gwesp(0.1,fixed=T), constraints = ~bd(maxout=10), control =
control.ergm(MCMLE.steplength = . 25, MCMC.burnin = 100000, MCMC.interval =
10000, MCMC.samplesize = 2500, MCMLE.maxit = 100), verbose=T)
```

Then the faux.desert.high dataset was created by simulating a single network from the above model fit:

```
faux.desert.high <- simulate(desert.fit, nsim=1,
    control=snctrl(MCMC.burnin=1e+8),
    constraints = ~edges)
```

When publishing results obtained using this data set, the original authors (Resnick et al, 1997) should be cited. In addition this package should be cited as:
Mark S. Handcock, David R. Hunter, Carter T. Butts, Steven M. Goodreau, and Martina Morris. 2003 statnet: Software tools for the Statistical Modeling of Network Data https://statnet.org.

## Source

The data set is based upon a model fit to data from two school communities from the AddHealth Study, Wave I (Resnick et al., 1997). It was constructed as follows:
The two schools in question (a junior and senior high school in the same community) were combined into a single network dataset. Students who did not take the AddHealth survey or who were not listed on the schools' student rosters were eliminated, then an undirected link was established between any two individuals who both named each other as a friend. All missing race, grade, and sex values were replaced by a random draw with weights determined by the size of the attribute classes in the school.

The following ergm model was fit to the original data:

```
magnolia.fit <- ergm (magnolia ~ edges +
nodematch("Grade",diff=T) + nodematch("Race",diff=T) +
nodematch("Sex",diff=F) + absdiff("Grade") + gwesp(0.25,fixed=T),
control=control.ergm(MCMC.burnin=10000, MCMC.interval=1000, MCMLE.maxit=25,
    MCMC.samplesize=2500, MCMLE.steplength=0.25))
```

Then the faux.magnolia.high dataset was created by simulating a single network from the above model fit:

```
faux.magnolia.high <- simulate (magnolia.fit, nsim=1,
    control = snctrl(MCMC.burnin=100000000), constraints = ~edges)
```

## See Also

network, plot.network, ergm, faux.mesa.high
faux.mesa.high Goodreau's Faux Mesa High School as a network object

## Description

This data set (formerly called "fauxhigh") represents a simulation of an in-school friendship network. The network is named faux.mesa.high because the school commnunity on which it is based is in the rural western US, with a student body that is largely Hispanic and Native American.

## Usage

data(faux.mesa.high)

## Format

faux.mesa.high is a network object with 205 vertices (students, in this case) and 203 undirected edges (mutual friendships). To obtain additional summary information about it, type summary (faux.mesa.high).

The vertex attributes are Grade, Sex, and Race. The Grade attribute has values 7 through 12, indicating each student's grade in school. The Race attribute is based on the answers to two questions, one on Hispanic identity and one on race, and takes six possible values: White (non-Hisp.), Black (non-Hisp.), Hispanic, Asian (non-Hisp.), Native American, and Other (non-Hisp.)

https://statnet.org.

## Source

The data set is based upon a model fit to data from one school community from the AddHealth Study, Wave I (Resnick et al., 1997). It was constructed as follows:

A vector representing the sex of each student in the school was randomly re-ordered. The same was done with the students' response to questions on race and grade. These three attribute vectors were permuted independently. Missing values for each were randomly assigned with weights determined by the size of the attribute classes in the school.

The following ergm formula was used to fit a model to the original data:

```
~ edges + nodefactor("Grade") + nodefactor("Race") +
nodefactor("Sex") + nodematch("Grade",diff=TRUE) +
nodematch("Race",diff=TRUE) + nodematch("Sex",diff=FALSE) +
gwdegree(1.0,fixed=TRUE) + gwesp(1.0,fixed=TRUE) + gwdsp(1.0,fixed=TRUE)
```

The resulting model fit was then applied to a network with actors possessing the permuted attributes and with the same number of edges as in the original data.
The processes for handling missing data and defining the race attribute are described in Hunter, Goodreau <br>\& Handcock (2008).

fix.curved Convert a curved ERGM into a corresponding "fixed" ERGM.

## Description

The generic fix.curved converts an ergm object or formula of a model with curved terms to the variant in which the curved parameters are fixed. Note that each term has to be treated as a special case.

## Usage

```
fix.curved(object, ...)
## S3 method for class 'ergm'
fix.curved(object, ...)
## S3 method for class 'formula'
fix.curved(object, theta, ...)
```

## Arguments

| object | An ergm object or an ERGM formula. The curved terms of the given formula <br> (or the formula used in the fit) must have all of their arguments passed by name. |
| :--- | :--- |
| $\ldots$ | Unused at this time. |
| theta | Curved model parameter configuration. |

## Details

Some ERGM terms such as gwesp and gwdegree have two forms: a curved form, for which their decay or similar parameters are to be estimated, and whose canonical statistics is a vector of the term's components (esp(1), esp(2), ... and degree(1), degree(2), ... respectively) and a "fixed" form where the decay or similar parameters are fixed, and whose canonical statistic is just the term itself. It is often desirable to fit a model estimating the curved parameters but simulate the "fixed" statistic.
This function thus takes in a fit or a formula and performs this mapping, returning a "fixed" model and parameter specification. It only works for curved ERGM terms included with the ergm package. It does not work with curved terms not included in ergm.

## Value

A list with the following components:

| formula | The "fixed" formula. |
| :--- | :--- |
| theta | The "fixed" parameter vector. |

## See Also

ergm, simulate.ergm

## Examples

```
data(sampson)
gest<-ergm(samplike~edges+gwesp(),
    control=control.ergm(MCMLE.maxit=2))
summary(gest)
# A statistic for esp(1),...,esp(16)
simulate(gest,output="stats")
```

```
tmp<-fix.curved(gest)
tmp
# A gwesp() statistic only
simulate(tmp$formula, coef=tmp$theta, output="stats")
```

fixallbut-ergmConstraint

Preserve the dyad status in all but the given edges

## Description

Preserve the dyad status in all but free. dyads.

## Usage

\# fixallbut(free.dyads)

## Arguments

free.dyads edgelist or network. Networks will be converted to the corresponding edgelist.

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

```
fixedas-ergmConstraint
                    Preserve and preclude edges
```

## Description

Preserve the edges in 'present' and preclude the edges in 'absent'.

## Usage

\# fixedas(present, absent)

## Arguments

present, absent
edgelist or network

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

## Description

This is a data set of marriage and business ties among Renaissance Florentine families. The data is originally from Padgett (1994) via UCINET and stored as a network object.

## Usage

data(florentine)

## Details

Breiger <br>\& Pattison (1986), in their discussion of local role analysis, use a subset of data on the social relations among Renaissance Florentine families (person aggregates) collected by John Padgett from historical documents. The two relations are business ties (flobusiness - specifically, recorded financial ties such as loans, credits and joint partnerships) and marriage alliances (flomarriage).
As Breiger $\backslash \&$ Pattison point out, the original data are symmetrically coded. This is acceptable perhaps for marital ties, but is unfortunate for the financial ties (which are almost certainly directed). To remedy this, the financial ties can be recoded as directed relations using some external measure of power - for instance, a measure of wealth. Both graphs provide vertex information on (1) weal th each family's net wealth in 1427 (in thousands of lira); (2) priorates the number of priorates (seats on the civic council) held between 1282-1344; and (3) totalties the total number of business or marriage ties in the total dataset of 116 families (see Breiger $\backslash \&$ Pattison (1986), p 239).

Substantively, the data include families who were locked in a struggle for political control of the city of Florence around 1430. Two factions were dominant in this struggle: one revolved around the infamous Medicis (9), the other around the powerful Strozzis (15).

## Description

This is an example thought of by Steve Goodreau. It is a directed network of four nodes and five ties stored as a network object.

## Usage

data(g4)

## Details

It is interesting because the maximum likelihood estimator of the model with out degree 3 in it exists, but the maximum psuedolikelihood estimator does not.

## Source

Steve Goodreau

## See Also

florentine, network, plot.network, ergm

## Examples

```
data(g4)
summary(ergm(g4 ~ odegree(3), estimate="MPLE"))
summary(ergm(g4 ~ odegree(3), control=control.ergm(init=0)))
```

```
geweke.diag.mv Multivariate version of coda's coda::geweke.diag().
```

## Description

Rather than comparing each mean independently, compares them jointly. Note that it returns an htest object, not a geweke. diag object.

## Usage

geweke.diag.mv(x, frac1 = 0.1, frac2 = 0.5, split.mcmc.list = FALSE, ...)

## Arguments

X
an mcmc, mcmc. list, or just a matrix with observations in rows and variables in columns.
frac1, frac2 the fraction at the start and, respectively, at the end of the sample to compare.
split.mcmc.list
when given an mcmc. list, whether to test each chain individually.
... additional arguments, passed on to approx.hotelling.diff.test(), which passes them to spectrum0.mvar (), etc.; in particular, order.max= can be used to limit the order of the AR model used to estimate the effective sample size.

## Value

An object of class htest, inheriting from that returned by approx. hotelling.diff.test(), but with p -value considered to be 0 on insufficient sample size.

## Note

If approx.hotelling.diff.test() returns an error, then assume that burn-in is insufficient.

## See Also

coda::geweke.diag(), approx. hotelling.diff.test()

```
gof Conduct Goodness-of-Fit Diagnostics on a Exponential Family Ran- dom Graph Model

)
## S3 method for class 'gof'
print(x, ...)
## S3 method for class 'gof'
plot(
    x,
    ...,
    cex.axis = 0.7,
    plotlogodds = FALSE,
    main = "Goodness-of-fit diagnostics",
    normalize.reachability = FALSE,
    verbose = FALSE
)
```

## Arguments

object Either a formula or an ergm object. See documentation for ergm.
... Additional arguments, to be passed to lower-level functions.
coef When given either a formula or an object of class ergm, coef are the parameters from which the sample is drawn. By default set to a vector of 0 .
GOF formula; an formula object, of the form ~ <model terms> specifying the statistics to use to diagnosis the goodness-of-fit of the model. They do not need to be in the model formula specified in formula, and typically are not. Currently supported terms are the degree distribution ("degree" for undirected graphs, "idegree" and/or "odegree" for directed graphs, and "b1degree" and "b2degree" for bipartite undirected graphs), geodesic distances ("distance"), shared partner distributions ("espartners" and "dspartners"), the triad census ("triadcensus"), and the terms of the original model ("model"). The default formula for undirected networks is $\sim$ degree + espartners + distance + model, and the default formula for directed networks is ~idegree + odegree + espartners + distance + model. By default a "model" term is added to the formula. It is a very useful overall validity check and a reminder of the statistical variation in the estimates
of the mean value parameters. To omit the "model" term, add "- model" to the formula.
constraints A one-sided formula specifying one or more constraints on the support of the distribution of the networks being modeled. See the help for similarly-named argument in ergm for more information. For gof. formula, defaults to unconstrained. For gof.ergm, defaults to the constraints with which object was fitted.
control A list of control parameters for algorithm tuning, typically constructed with control.gof.formula() or control.gof.ergm(), which have different defaults. Their documentation gives the the list of recognized control parameters and their meaning. The more generic utility snctrl() (StatNet ConTRoL) also provides argument completion for the available control functions and limited argument name checking.
verbose A logical or an integer to control the amount of progress and diagnostic information to be printed. FALSE/0 produces minimal output, wit higher values producing more detail. Note that very high values (5+) may significantly slow down processing.
basis a value (usually a network) to override the LHS of the formula.
unconditional logical; if TRUE, the simulation is unconditional on the observed dyads. if not TRUE, the simulation is conditional on the observed dyads. This is primarily used internally when the network has missing data and a conditional GoF is produced.
$x \quad$ an object of class gof for printing or plotting.
cex.axis Character expansion of the axis labels relative to that for the plot.
plotlogodds Plot the odds of a dyad having given characteristics (e.g., reachability, minimum geodesic distance, shared partners). This is an alternative to the probability of a dyad having the same property.
main Title for the goodness-of-fit plots.
normalize.reachability
Should the reachability proportion be normalized to make it more comparable with the other geodesic distance proportions.

## Details

A sample of graphs is randomly drawn from the specified model. The first argument is typically the output of a call to ergm and the model used for that call is the one fit.
For GOF = ~model, the model's observed sufficient statistics are plotted as quantiles of the simulated sample. In a good fit, the observed statistics should be near the sample median (0.5).

By default, the sample consists of 100 simulated networks, but this sample size (and many other settings) can be changed using the control argument described above.

## Value

gof, gof.ergm, and gof.formula return an object of class gof.ergm, which inherits from class gof. This is a list of the tables of statistics and $p$-values. This is typically plotted using plot.gof.

## Methods (by class)

- ergm: Perform simulation to evaluate goodness-of-fit for a specific ergm() fit.
- formula: Perform simulation to evaluate goodness-of-fit for a model configuration specified by a formula, coefficient, constraints, and other settings.
- gof: print.gof summaries the diagnostics such as the degree distribution, geodesic distances, shared partner distributions, and reachability for the goodness-of-fit of exponential family random graph models. See ergm for more information on these models. (summary.gof is a deprecated alias that may be repurposed in the future.)
- gof: plot.gof plots diagnostics such as the degree distribution, geodesic distances, shared partner distributions, and reachability for the goodness-of-fit of exponential family random graph models. See ergm for more information on these models.

## Note

For gof.ergm and gof.formula, default behavior depends on the directedness of the network involved; if undirected then degree, espartners, and distance are used as default properties to examine. If the network in question is directed, "degree" in the above is replaced by idegree and odegree.

# test the gof.ergm function
gofflo <- gof(gest)
gofflo
# Plot all three on the same page
# with nice margins
par(mfrow=c(1,3))
par(oma=c(0.5, 2, 1, 0.5))
plot(gofflo)
# And now the log-odds
plot(gofflo, plotlogodds=TRUE)
# Use the formula version of gof
gofflo2 <-gof(flomarriage ~ edges + kstar(2), coef=c(-1.6339, 0.0049))
plot(gofflo2)
```

greaterthan-ergmTerm Number of dyads with values strictly greater than a threshold

## Description

Adds the number of statistics equal to the length of threshold equaling to the number of dyads whose values exceed the corresponding element of threshold.

## Usage

\# valued: greaterthan(threshold=0)

## Arguments

threshold a vector of numerical values

## See Also

ergmTerm for index of model terms currently visible to the package.
gwb1degree-ergmTerm Geometrically weighted degree distribution for the first mode in a bipartite network

## Description

This term adds one network statistic to the model equal to the weighted degree distribution with decay controlled by the decay parameter, which should be non-negative, for nodes in the first mode of a bipartite network. The first mode of a bipartite network object is sometimes known as the "actor" mode.
This term can only be used with undirected bipartite networks.

## Usage

\# binary: gwb1degree(decay, fixed=FALSE, attr=NULL, cutoff=30, levels=NULL)

## Arguments

decay nonnegative decay parameter for the first mode degree frequencies; required if fixed=TRUE and ignored with a warning otherwise.
fixed optional argument indicating whether the decay parameter is fixed at the given value, or is to be fit as a curved exponential-family model (see Hunter and Handcock, 2006). The default is FALSE , which means the scale parameter is not fixed and thus the model is a curved exponential family.

| attr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) |
| :--- | :--- |
| cutoff | This optional argument sets the number of underlying degree terms to use in <br> computing the statistics when fixed=FALSE, in order to reduce the computa- <br> tional burden. Its default value can also be controlled by the gw.cutoff term <br> option control parameter. (See ?control.ergm.) |
| levels | TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for <br> details.) |

## See Also

gwb1dsp-ergmTerm | Geometrically weighted dyadwise shared partner distribution for |
| :--- |
| dyads in the first bipartition |

## Description

This term adds one network statistic to the model equal to the geometrically weighted dyadwise shared partner distribution for dyads in the first bipartition with decay parameter decay parameter, which should be non-negative. This term can only be used with bipartite networks.

## Usage

\# binary: gwb1dsp(decay=0, fixed=FALSE, cutoff=30)

## Arguments

decay nonnegative decay parameter for the shared partner counts; required if fixed=TRUE and ignored with a warning otherwise.
fixed optional argument indicating whether the decay parameter is fixed at the given value, or is to be fit as a curved exponential-family model (see Hunter and Handcock, 2006). The default is FALSE, which means the scale parameter is not fixed and thus the model is a curved exponential family.
cutoff This optional argument sets the number of underlying b1dsp terms to use in computing the statistics when fixed=FALSE, in order to reduce the computational burden. Its default value can also be controlled by the gw. cutoff term option control parameter. (See ?control.ergm.)

## See Also

ergmTerm for index of model terms currently visible to the package.

```
gwb2degree-ergmTerm
Geometrically weighted degree distribution for the second mode in a
bipartite network
```

## Description

This term adds one network statistic to the model equal to the weighted degree distribution with decay controlled by the which should be non-negative, for nodes in the second mode of a bipartite network. The second mode of a bipartite network object is sometimes known as the "event" mode.

## Usage

\# binary: gwb2degree(decay, fixed=FALSE, attr=NULL, cutoff=30, levels=NULL)

## Arguments

| decay | nonnegative decay parameter for the second mode degree frequencies; required <br> if fixed=TRUE and ignored with a warning otherwise. |
| :--- | :--- |
| fixed | optional argument indicating whether the decay parameter is fixed at the given <br> value, or is to be fit as a curved exponential-family model (see Hunter and Hand- <br> cock, 2006). The default is FALSE, which means the scale parameter is not fixed <br> and thus the model is a curved exponential family. <br> quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) |
| cuttr | This optional argument sets the number of underlying degree terms to use in <br> computing the statistics when fixed=FALSE, in order to reduce the computa- <br> tional burden. Its default value can also be controlled by the gw.cutoff term <br> option control parameter. (See ?control.ergm.) |
| levels | TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for <br> details.) |

gwdsp-ergmTerm Geometrically weighted dyadwise shared partner distribution

## Description

This term adds one network statistic to the model equal to the geometrically weighted dyadwise shared partner distribution with decay parameter decay parameter, which should be non-negative. This term can be used with directed and undirected networks.

## Usage

\# binary: gwdsp(decay, fixed=FALSE, cutoff=30)

## Arguments

$$
\begin{array}{ll}
\text { decay } & \begin{array}{l}
\text { nonnegative decay parameter for the shared partner or directed 2-path count; } \\
\text { required if fixed=TRUE and ignored with a warning otherwise. }
\end{array} \\
\text { fixed } & \begin{array}{l}
\text { optional argument indicating whether the decay parameter is fixed at the given } \\
\text { value, or is to be fit as a curved exponential-family model (see Hunter and Hand- } \\
\text { cock, 2006). The default is FALSE, which means the scale parameter is not fixed } \\
\text { and thus the model is a curved exponential family. }
\end{array} \\
\text { cutoff } & \begin{array}{l}
\text { This optional argument sets the number of underlying DSP terms to use in com- } \\
\text { puting the statistics when fixed=FALSE, in order to reduce the computational } \\
\text { burden. Its default value can also be controlled by the gw. cutoff term option } \\
\text { control parameter. (See ?control.ergm.) }
\end{array}
\end{array}
$$

## Note

For directed networks, only outgoing two-path ("OTP") shared partners are counted. In other words, for a (directed) dyad ( $i, j$ ) in a directed graph, the number of shared partners counted by gwdsp is the number of nodes $k$ that have edges $i->k->j$. (These may also be called homogeneous shared partners.) To count other types of shared partners instead, see dgwdsp.
The decay parameter was called alpha prior to ergm 3.7.

## See Also

ergmTerm for index of model terms currently visible to the package.
gwesp-ergmTerm Geometrically weighted edgewise shared partner distribution

## Description

This term is just like gwdsp except it adds a statistic equal to the geometrically weighted edgewise (not dyadwise) shared partner distribution with decay parameter decay parameter, which should be non-negative. This term can be used with directed and undirected networks.

## Usage

\# binary: gwesp(decay, fixed=FALSE, cutoff=30)

## Arguments

> decay nonnegative decay parameter for the shared partner or directed 2-path count; required if fixed=TRUE and ignored with a warning otherwise.
> fixed optional argument indicating whether the decay parameter is fixed at the given value, or is to be fit as a curved exponential-family model (see Hunter and Handcock, 2006). The default is FALSE , which means the scale parameter is not fixed and thus the model is a curved exponential family.
> cutoff This optional argument sets the number of underlying ESP terms to use in computing the statistics when fixed=FALSE, in order to reduce the computational burden. Its default value can also be controlled by the gw. cutoff term option control parameter. (See ?control.ergm.)

## Note

For directed networks, only outgoing two-path ("OTP") shared partners are counted. In other words, for a (directed) edge $\mathrm{i}->\mathrm{j}$ in a directed graph, the number of shared partners counted by gwesp is the number of nodes $k$ that have edges $i->k->j$. (These may also be called homogeneous shared partners.) To count other types of shared partners instead, see dgwesp.
The decay parameter was called alpha prior to ergm 3.7.

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

This term adds one network statistic to the model equal to the weighted in-degree distribution with decay parameter decay parameter, which should be non-negative. This term can only be used with directed networks.

## Usage

\# binary: gwidegree(decay, fixed=FALSE, attr=NULL, cutoff=30, levels=NULL)

## Arguments

| decay | nonnegative decay parameter for the indegree frequencies; required if fixed=TRUE <br> and ignored with a warning otherwise. |
| :--- | :--- |
| fixed | optional argument indicating whether the decay parameter is fixed at the given <br> value, or is to be fit as a curved exponential-family model (see Hunter and Hand- <br> cock, 2006). The default is FALSE, which means the scale parameter is not fixed <br> and thus the model is a curved exponential family. |
| attr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) |
| cutoff | This optional argument sets the number of underlying degree terms to use in <br> computing the statistics when fixed=FALSE, in order to reduce the computa- <br> tional burden. Its default value can also be controlled by the gw.cutoff term <br> option control parameter. (See ?control.ergm.) |
| levels | TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for <br> details.) |

## See Also

ergmTerm for index of model terms currently visible to the package.
gwnsp-ergmTerm Geometrically weighted nonedgewise shared partner distribution

## Description

This term is just like gwesp and gwdsp except it adds a statistic equal to the geometrically weighted nonedgewise (that is, over dyads that do not have an edge) shared partner distribution with weight parameter decay parameter, which should be non-negative. This term can be used with directed and undirected networks.

## Usage

\# binary: gwnsp(decay, fixed=FALSE, cutoff=30)

## Arguments

$$
\begin{array}{ll}
\text { decay } & \begin{array}{l}
\text { nonnegative decay parameter for the shared partner or directed 2-path count; } \\
\text { required if fixed=TRUE and ignored with a warning otherwise. }
\end{array} \\
\text { fixed } & \begin{array}{l}
\text { optional argument indicating whether the decay parameter is fixed at the given } \\
\text { value, or is to be fit as a curved exponential-family model (see Hunter and Hand- } \\
\text { cock, 2006). The default is FALSE, which means the scale parameter is not fixed } \\
\text { and thus the model is a curved exponential family. }
\end{array} \\
\text { cutoff } & \begin{array}{l}
\text { This optional argument sets the number of underlying NSP terms to use in com- } \\
\text { puting the statistics when fixed=FALSE, in order to reduce the computational } \\
\text { burden. Its default value can also be controlled by the gw. cutoff term option } \\
\text { control parameter. (See ?control.ergm.) }
\end{array}
\end{array}
$$

## Note

For directed networks, only outgoing two-path ("OTP") shared partners are counted. In other words, for a (directed) non-edge ( $i, j$ ) in a directed graph, the number of shared partners counted by gwnsp is the number of nodes $k$ that have edges $i \rightarrow k \rightarrow j$. (These may also be called homogeneous shared partners.) To count other types of shared partners instead, see dgwnsp.
The decay parameter was called alpha prior to ergm 3.7.

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

This term adds one network statistic to the model equal to the weighted out-degree distribution with decay parameter decay parameter, which should be non-negative. This term can only be used with directed networks.

## Usage

\# binary: gwodegree(decay, fixed=FALSE, attr=NULL, cutoff=30, levels=NULL)

## Arguments

| decay | nonnegative decay parameter for the outdegree frequencies; required if fixed=TRUE <br> and ignored with a warning otherwise. |
| :--- | :--- |
| fixed | optional argument indicating whether the decay parameter is fixed at the given <br> value, or is to be fit as a curved exponential-family model (see Hunter and Hand- <br> cock, 2006). The default is FALSE, which means the scale parameter is not fixed <br> and thus the model is a curved exponential family. |
| attr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) |
| cutoff | This optional argument sets the number of underlying degree terms to use in <br> computing the statistics when fixed=FALSE, in order to reduce the computa- <br> tional burden. Its default value can also be controlled by the gw.cutoff term <br> option control parameter. (See ?control. ergm.) |
| levels | TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for <br> details.) |

```
hamming-ergmConstraint
```

Preserve the hamming distance to the given network (BROKEN: Do NOT Use)

## Description

This constraint is currently broken. Do not use.

## Usage

\# hamming

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

## Description

This term adds one statistic to the model equal to the weighted or unweighted Hamming distance of the network from the network specified by x . Unweighted Hamming distance is defined as the total number of pairs $(i, j)$ (ordered or unordered, depending on whether the network is directed or undirected) on which the two networks differ. If the optional argument cov is specified, then the weighted Hamming distance is computed instead, where each pair $(i, j)$ contributes a pre-specified weight toward the distance when the two networks differ on that pair.

## Usage

\# binary: hamming(x, cov, attrname=NULL)

## Arguments

$x \quad$ defaults to be the observed network, i.e., the network on the left side of the $\sim$ in the formula that defines the ERGM.
cov either a matrix of edgewise weights or a network
attrname option argument that provides the name of the edge attribute to use for weight values when a network is specified in cov

```

## Description

This term adds one network statistic to the model for each element of from (or to ); the $i$ th such statistic equals the number of nodes in the network of in-degree greater than or equal to from[i] but strictly less than to[i], i.e. with in-edge count in semiopen interval [from, to) .
This term can only be used with directed networks; for undirected networks (bipartite and not) see degrange. For degrees of specific modes of bipartite networks, see b1degrange and b2degrange . For in-degrees, see idegrange .

## Usage

\# binary: idegrange(from, to=+Inf, by=NULL, homophily=FALSE, levels=NULL)

## Arguments

from, to vectors of distinct integers. If one of the vectors have length 1 , it is recycled to the length of the other. Otherwise, it must have the same length.
by, homophily the optional argument by specifies a vertex attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details). If this is specified and homophily is TRUE, then degrees are calculated using the subnetwork consisting of only edges whose endpoints have the same value of the by attribute. If by is specified and homophily is FALSE (the default), then separate degree range statistics are calculated for nodes having each separate value of the attribute.
levels TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)

## See Also

ergmTerm for index of model terms currently visible to the package.

```
idegree-ergmTerm In-degree
```

## Description

This term adds one network statistic to the model for each element in d ; the $i$ th such statistic equals the number of nodes in the network of in-degree $d[i]$, i.e. the number of nodes with exactly $d[i]$ in-edges. This term can only be used with directed networks; for undirected networks see degree .

## Usage

\# binary: idegree(d, by=NULL, homophily=FALSE, levels=NULL)

## Arguments

$$
\begin{array}{ll}
\mathrm{d} \\
\text { by, homophily } & \begin{array}{l}
\text { a vector of distinct integers } \\
\text { the optional argument by specifies a vertex attribute (see Specifying Vertex at- } \\
\text { tributes and Levels (?nodal_attributes) for details). If this is specified and } \\
\text { homophily is TRUE, then degrees are calculated using the subnetwork consist- } \\
\text { ing of only edges whose endpoints have the same value of the by attribute. If } \\
\text { by is specified and homophily is FALSE (the default), then separate degree range } \\
\text { statistics are calculated for nodes having each separate value of the attribute. }
\end{array} \\
\text { levels } & \begin{array}{l}
\text { TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for } \\
\text { details.) }
\end{array}
\end{array}
$$

## See Also

ergmTerm for index of model terms currently visible to the package.
idegree1.5-ergmTerm In-degree to the 3/2 power

## Description

This term adds one network statistic to the model equaling the sum over the actors of each actor's indegree taken to the $3 / 2$ power (or, equivalently, multiplied by its square root). This term is analogous to the term of Snijders et al. (2010), equation (12). This term can only be used with directed networks.

## Usage

\# binary: idegree1.5

## See Also

ergmTerm for index of model terms currently visible to the package.

```
    idegreedist-ergmConstraint
```

Preserve the indegree distribution

## Description

Preserve the indegree distribution of the given network.

## Usage

\# idegreedist

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

```
idegrees-ergmConstraint
```

    Preserve indegree for directed networks
    
## Description

For directed networks, preserve the indegree of each vertex of the given network, while allowing outdegree to vary

## Usage

\# idegrees

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.
ininterval-ergmTerm Number of dyads whose values are in an interval

## Description

Adds one statistic equaling to the number of dyads whose values are between lower and upper.

## Usage

\# valued: ininterval(lower=-Inf, upper=+Inf, open=c(TRUE,TRUE))

## Arguments

lower defaults to -Inf
upper defaults to $+\operatorname{Inf}$
open a logical vector of length 2 that controls whether the interval is open (exclusive) on the lower and on the upper end, respectively. open can also be specified as one of "[]" , " (]" , "[)", and " ()".

## See Also

ergmTerm for index of model terms currently visible to the package.

InitErgmTerm.threepath

## Three-trails

## Description

For an undirected network, this term adds one statistic equal to the number of 3-trails, where a 3trail is defined as a trail of length three that traverses three distinct edges. Note that a 3-trail need not include four distinct nodes; in particular, a triangle counts as three 3-trails. For a directed network, this term adds four statistics (or some subset of these four), one for each of the four distinct types of directed three-paths. If the nodes of the path are written from left to right such that the middle edge points to the right $(\mathrm{R})$, then the four types are RRR, RRL, LRR, and LRL. That is, an RRR 3-trail is of the form $i \rightarrow j \rightarrow k \rightarrow l$, and RRL 3-trail is of the form $i \rightarrow j \rightarrow k \leftarrow l$, etc. Like in the undirected case, there is no requirement that the nodes be distinct in a directed 3-trail. However, the three edges must all be distinct. Thus, a mutual tie $i \leftrightarrow j$ does not count as a 3-trail of the form $i \rightarrow j \rightarrow i \leftarrow j$; however, in the subnetwork $i \leftrightarrow j \rightarrow k$, there are two directed 3-trails, one LRR $(k \leftarrow j \rightarrow i \leftarrow j)$ and one $\operatorname{RRR}(j \rightarrow i \rightarrow j \leftarrow k)$.

```
Usage
    # binary: threepath
    # binary: threetrail(keep=NULL, levels=NULL)
```

## Arguments

keep deprecated
levels specify a subset of the four statistics for directed networks. (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)

## Note

The argument keep is retained for backwards compatibility and may be removed in a future version. When both keep and levels are passed, levels overrides keep.

This term used to be (inaccurately) called threepath. That name has been deprecated and may be removed in a future version.

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

This term adds one statistic to the model, equal to the number of triads in the network that are intransitive. The intransitive triads are those of type 111D, 201, 111U, 021C , or 030C in the categorization of Davis and Leinhardt (1972). For details on the 16 possible triad types, see triad.classify in the sna package. Note the distinction from the ctriple term.

## Usage

\# binary: intransitive

## Note

This term can only be used with directed networks.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
is.curved Testing for curved exponential family
```

## Description

These functions test whether an ERGM fit, formula, or some other object represents a curved exponential family.

The method for NULL always returns FALSE by convention.

## Usage

is.curved(object, ...)
\#\# S3 method for class '-NULL`'
is.curved(object, ...)
\#\# S3 method for class 'formula'
is.curved(object, response $=$ NULL, basis $=$ NULL, ...)
\#\# S3 method for class 'ergm'
is.curved(object, ...)

## Arguments

object An ergm object or an ERGM formula.
...
response
basis See ergm().

## Details

Curvature is checked by testing if all model parameters are canonical.

## Value

TRUE if the object represents a curved exponential family; FALSE otherwise.
is.dyad.independent Testing for dyad-independence

## Description

These functions test whether an ERGM fit, a formula, or some other object represents a dyadindependent model.
The method for NULL always returns TRUE by convention.

## Usage

```
    is.dyad.independent(object, ...)
    ## S3 method for class '`NULL`'
    is.dyad.independent(object, ...)
    ## S3 method for class 'formula'
    is.dyad.independent(object, response = NULL, basis = NULL, ...)
```

```
## S3 method for class 'ergm_conlist'
is.dyad.independent(object, object.obs = NULL, ...)
## S3 method for class 'ergm'
is.dyad.independent(object, ...)
```

## Arguments

object The object to be tested for dyadic independence.
... Unused at this time.
response Either a character string, a formula, or NULL (the default), to specify the response attributes and whether the ERGM is binary or valued. Interpreted as follows:
NULL Model simple presence or absence, via a binary ERGM.
character string The name of the edge attribute whose value is to be modeled.
Type of ERGM will be determined by whether the attribute is logical (TRUE/FALSE) for binary or numeric for valued.
a formula must be of the form NAME~EXPR |TYPE (with | being literal). EXPR is evaluated in the formula's environment with the network's edge attributes accessible as variables. The optional NAME specifies the name of the edge attribute into which the results should be stored, with the default being a concise version of EXPR. Normally, the type of ERGM is determined by whether the result of evaluating EXPR is logical or numeric, but the optional TYPE can be used to override by specifying a scalar of the type involved (e.g., TRUE for binary and 1 for valued).
basis See ergm.
object.obs For the ergm_conlist method, the observed data constraint.

## Details

Dyad independence is determined by checking if all of the constituent parts of the object (formula, ergm terms, constraints, etc.) are flagged as dyad-independent.

## Value

TRUE if the model implied by the object is dyad-independent; FALSE otherwise.

## Description

Function to check whether an ERGM fit or some aspect of it is valued

## Usage

```
is.valued(object, ...)
## S3 method for class 'ergm_state'
is.valued(object, ...)
## S3 method for class 'edgelist'
is.valued(object, ...)
## S3 method for class 'ergm'
is.valued(object, ...)
## S3 method for class 'network'
is.valued(object, ...)
```

## Arguments

object the object to be tested.
.. additional arguments for methods, currently unused.

## Methods (by class)

- ergm_state: a method for ergm_state objects.
- edgelist: a method for edgelist objects.
- ergm: a method for ergm objects.
- network: a method for network objects that tests whether the network has been instrumented with a valued \%ergmlhs\% "response" specification, typically by ergm_preprocess_response(). Note that it is not a test for whether a network has edge attributes. This method is primarily for internal use.

```
isolatededges-ergmTerm
```

## Isolated edges

## Description

This term adds one statistic to the model equal to the number of isolated edges in the network, i.e., the number of edges each of whose endpoints has degree 1 . This term can only be used with undirected networks.

## Usage <br> \# binary: isolatededges

## See Also

ergmTerm for index of model terms currently visible to the package.

```
    isolates-ergmTerm Isolates
```

## Description

This term adds one statistic to the model equal to the number of isolates in the network. For an undirected network, an isolate is defined to be any node with degree zero. For a directed network, an isolate is any node with both in-degree and out-degree equal to zero.

## Usage

\# binary: isolates

## See Also

ergmTerm for index of model terms currently visible to the package.

```
istar-ergmTerm In-stars
```

## Description

This term adds one network statistic to the model for each element in k . The $i$ th such statistic counts the number of distinct $\mathrm{k}[\mathrm{i}]$-instars in the network, where a $k$-instar is defined to be a node $N$ and a set of $k$ different nodes $\left\{O_{1}, \ldots, O_{k}\right\}$ such that the ties $\left(O_{j} \rightarrow N\right)$ exist for $j=1, \ldots, k$. If attr is specified then the count is over the number of $k$-instars where all nodes have the same value of the attribute. This term can only be used for directed networks; for undirected networks see kstar. Note that istar(1) is equal to both ostar (1) and edges .

## Usage

\# binary: istar(k, attr=NULL, levels=NULL)

## Arguments

| k | a vector of distinct integers |
| :--- | :--- |
| attr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) |
| levels | TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for <br> details.) |

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

This well-known social network dataset, collected by Bruce Kapferer in Zambia from June 1965 to August 1965, involves interactions among workers in a tailor shop as observed by Kapferer himself.

## Usage <br> data(kapferer)

## Format

Two network objects, kapferer and kapferer2. The kapferer dataset contains only the 39 individuals who were present at both data-collection time periods. However, these data only reflect data collected during the first period. The individuals' names are included as a nodal covariate called names.

## Details

An interaction is defined by Kapferer as "continuous uninterrupted social activity involving the participation of at least two persons"; only transactions that were relatively frequent are recorded. All of the interactions in this particular dataset are "sociational", as opposed to "instrumental". Kapferer explains the difference (p. 164) as follows:
"I have classed as transactions which were sociational in content those where the activity was markedly convivial such as general conversation, the sharing of gossip and the enjoyment of a drink together. Examples of instrumental transactions are the lending or giving of money, assistance at times of personal crisis and help at work."
Kapferer also observed and recorded instrumental transactions, many of which are unilateral (directed) rather than reciprocal (undirected), though those transactions are not recorded here. In addition, there was a second period of data collection, from September 1965 to January 1966, but these data are also not recorded here. All data are given in Kapferer's 1972 book on pp. 176-179.
During the first time period, there were 43 individuals working in this particular tailor shop; however, the better-known dataset includes only those 39 individuals who were present during both time collection periods. (Missing are the workers named Lenard, Peter, Lazarus, and Laurent.) Thus, we give two separate network datasets here: kapferer is the well-known 39-individual dataset, whereas kapferer 2 is the full 43-individual dataset.

## Source

Original source: Kapferer, Bruce (1972), Strategy and Transaction in an African Factory, Manchester University Press.

## Description

This term adds one network statistic to the model for each element in k . The $i$ th such statistic counts the number of distinct $\mathrm{k}[\mathrm{i}]$-stars in the network, where a $k$-star is defined to be a node $N$ and a set of $k$ different nodes $\left\{O_{1}, \ldots, O_{k}\right\}$ such that the ties $\left\{N, O_{i}\right\}$ exist for $i=1, \ldots, k$. If this is specified then the count is over the number of $k$-stars where all nodes have the same value of the attribute. This term can only be used for undirected networks; for directed networks, see istar , ostar, twopath and m2star. Note that kstar (1) is equal to edges.

## Usage

\# binary: kstar(k, attr=NULL, levels=NULL)

## Arguments

| k | a vector of distinct integers |
| :--- | :--- |
| attr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) |
| levels | TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for <br> details.) |

## See Also

ergmTerm for index of model terms currently visible to the package.
Label-ergmTerm Modify terms' coefficient names

## Description

This operator evaluates formula without modification, but modifies its coefficient and/or parameter names based on label and pos.

## Usage

\# binary: Label(formula, label, pos)
\# valued: Label(formula, label, pos)

## Arguments

formula a one-sided ergm()-style formula with the terms to be evaluated
label either a character vector specifying the label for the terms or a function through which term names are mapped (or a as_mapper -style formula).
pos controls how label modifies the term names: one of "prepend" , "replace", "append", or " (" , with the latter wrapping the term names in parentheses like a function call with name specified by label.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
localtriangle-ergmTerm
```

## Triangles within neighborhoods

## Description

This term adds one statistic to the model equal to the number of triangles in the network between nodes "close to" each other. For an undirected network, a local triangle is defined to be any set of three edges between nodal pairs $\{(i, j),(j, k),(k, i)\}$ that are in the same neighborhood. For a directed network, a triangle is defined as any set of three edges $(i \rightarrow j),(j \rightarrow k)$ and either $(k \rightarrow i)$ or $(k \leftarrow i)$ where again all nodes are within the same neighborhood.

## Usage

\# binary: localtriangle(x)

## Arguments

x
an undirected network or an symmetric adjacency matrix that specifies whether the two nodes are in the same neighborhood. Note that triangle, with or without an argument, is a special case of localtriangle.

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

Evaluate the terms specified in formula and takes a natural (base e) logarithm of them. Since an ERGM statistic must be finite, $\log 0$ specifies the value to be substituted for $\log (0)$. The default value seems reasonable for most purposes.

## Usage

\# binary: Log(formula, log0=-1/sqrt(.Machine\$double.eps))
\# valued: Log(formula, log0=-1/sqrt(.Machine\$double.eps))

## Arguments

| formula | a one-sided $\operatorname{ergm}()$-style formula with the terms to be evaluated |
| :--- | :--- |
| $\log 0$ | the value to be substituted for $\log (0)$ |

## See Also

ergmTerm for index of model terms currently visible to the package.

```
logLik.ergm A logLik method for ergm fits.
```

## Description

A function to return the log-likelihood associated with an ergm fit, evaluating it if necessary. If the log-likelihood was not computed for object, produces an error unless eval.loglik=TRUE.

## Usage

```
## S3 method for class 'ergm'
logLik(
    object,
    add = FALSE,
    force.reeval = FALSE,
    eval.loglik = add || force.reeval,
    control = control.logLik.ergm(),
    )
    ## S3 method for class 'ergm'
```

```
deviance(object, ...)
## S3 method for class 'ergm'
AIC(object, ..., k = 2)
## S3 method for class 'ergm'
BIC(object, ...)
```

## Arguments

object An ergm fit, returned by ergm.
add Logical: If TRUE, instead of returning the log-likelihood, return object with log-likelihood value (and the null likelihood value) set.
force.reeval Logical: If TRUE, reestimate the log-likelihood even if object already has an estiamte.
eval. loglik Logical: If TRUE, evaluate the log-likelihood if not set on object.
control A list of control parameters for algorithm tuning, typically constructed with control. logLik.ergm(). Its documentation gives the the list of recognized control parameters and their meaning. The more generic utility snctrl() (StatNet ConTRoL) also provides argument completion for the available control functions and limited argument name checking.
... Other arguments to the likelihood functions.
$k \quad$ see help for AIC().

## Value

The form of the output of logLik. ergm depends on add: add=FALSE (the default), a logLik object. If add=TRUE (the default), an ergm object with the log-likelihood set.
As of version 3.1, all likelihoods for which logLikNull is not implemented are computed relative to the reference measure. (I.e., a null model, with no terms, is defined to have likelihood of 0 , and all other models are defined relative to that.)

## Functions

- deviance.ergm: A deviance() method.
- AIC.ergm: An AIC() method.
- BIC.ergm: A BIC() method.

## Examples

```
# See help(ergm) for a description of this model. The likelihood will
# not be evaluated.
data(florentine)
## Not run:
# The default maximum number of iterations is currently 20. We'll only
# use 2 here for speed's sake.
gest <- ergm(flomarriage ~ kstar(1:2) + absdiff("wealth") + triangle, eval.loglik=FALSE)
gest <- ergm(flomarriage ~ kstar(1:2) + absdiff("wealth") + triangle, eval.loglik=FALSE,
    control=control.ergm(MCMLE.maxit=2))
    # Log-likelihood is not evaluated, so no deviance, AIC, or BIC:
    summary(gest)
    # Evaluate the log-likelihood and attach it to the object.
    # The default number of bridges is currently 20. We'll only use 3 here
    # for speed's sake.
    gest.logLik <- logLik(gest, add=TRUE)
    gest.logLik <- logLik(gest, add=TRUE, control=control.logLik.ergm(bridge.nsteps=3))
    # Deviances, AIC, and BIC are now shown:
    summary(gest.logLik)
    # Null model likelihood can also be evaluated, but not for all constraints:
    logLikNull(gest) # == network.dyadcount(flomarriage)*log(1/2)
    ## End(Not run)
```

    logLikNull
        Calculate the null model likelihood
    
## Description

Calculate the null model likelihood

## Usage

logLikNull(object, ...)
\#\# S3 method for class 'ergm'
logLikNull(object, control = control.logLik.ergm(), ...)

## Arguments

object a fitted model.
... further arguments to lower-level functions.
logLikNull computes, when possible the log-probability of the data under the null model (reference distribution).
control A list of control parameters for algorithm tuning, typically constructed with control.logLik.ergm(). Its documentation gives the the list of recognized control parameters and their meaning. The more generic utility snctrl() (StatNet ConTRoL) also provides argument completion for the available control functions and limited argument name checking.

## Value

logLikNull returns an object of type logLik if it is able to compute the null model probability, and NA otherwise.

## Methods (by class)

- ergm: A method for ergm fits; currently only implemented for binary ERGMs with dyadindependent sample-space constraints.

```
m2star-ergmTerm Mixed 2-stars, a.k.a 2-paths
```

## Description

This term adds one statistic to the model, equal to the number of mixed 2 -stars in the network, where a mixed 2-star is a pair of distinct edges $(i \rightarrow j),(j \rightarrow k)$. A mixed 2-star is sometimes called a 2-path because it is a directed path of length 2 from $i$ to $k$ via $j$. However, in the case of a 2-path the focus is usually on the endpoints $i$ and $k$, whereas for a mixed 2 -star the focus is usually on the midpoint $j$. This term can only be used with directed networks; for undirected networks see kstar (2). See also twopath .

## Usage

\# binary: m2star

## See Also

ergmTerm for index of model terms currently visible to the package.

```
mcmc.diagnostics Conduct MCMC diagnostics on a model fit
```

## Description

This function prints diagnistic information and creates simple diagnostic plots for MCMC sampled statistics produced from a fit.

## Usage

```
mcmc.diagnostics(object, ...)
    ## S3 method for class 'ergm'
    mcmc.diagnostics(
        object,
        center = TRUE,
        esteq = TRUE,
        vars.per.page = 3,
        which = c("plots", "texts", "summary", "autocorrelation", "crosscorrelation",
            "burnin"),
    )
```

## Arguments

object A model fit object to be diagnosed.
... Additional arguments, to be passed to plotting functions.
center Logical: If TRUE, center the samples on the observed statistics.
esteq Logical: If TRUE, for statistics corresponding to curved ERGM terms, summarize the curved statistics by their negated estimating function values (evaluated at the MLE of any curved parameters) (i.e., $\eta_{I}^{\prime}(\hat{\theta}) \cdot\left(g_{I}(Y)-g_{I}(y)\right)$ for $I$ being indices of the canonical parameters in question), rather than the canonical (sufficient) vectors of the curved statistics relative to the observed $\left(g_{I}(Y)-g_{I}(y)\right)$.
vars.per.page Number of rows (one variable per row) per plotting page. Ignored if latticeExtra package is not installed.
which A character vector specifying which diagnostics to plot and/or print. Defaults to all of the below if meaningful:
"plots" Traceplots and density plots of sample values for all statistic or estimating function elements.
"texts" Shorthand for the following text diagnostics.
"summary" Summary of network statistic or estimating function elements as produced by coda: : summary.mcmc.list().
"autocorrelation" Autocorrelation of each of the network statistic or estimating function elements.
"crosscorrelation" Cross-correlations between each pair of the network statistic or estimating function elements.
"burnin" Burn-in diagnostics, in particular, the Geweke test.
Partial matching is supported. (E.g., which=c("auto", "cross") will print autocorrelation and cross-correlations.)

## Details

A pair of plots are produced for each statistic:a trace of the sampled output statistic values on the left and density estimate for each variable in the MCMC chain on the right. Diagnostics printed to the console include correlations and convergence diagnostics.

For ergm() specifically, recent changes in the estimation algorithm mean that these plots can no longer be used to ensure that the mean statistics from the model match the observed network statistics. For that functionality, please use the GOF command: gof (object, GOF=~model).
In fact, an ergm output object contains the matrix of statistics from the MCMC run as component \$sample. This matrix is actually an object of class mcmc and can be used directly in the coda package to assess MCMC convergence. Hence all MCMC diagnostic methods available in coda are available directly. See the examples and https://www.mrc-bsu.cam.ac.uk/software/bugs/ the-bugs-project-winbugs/coda-readme/.
More information can be found by looking at the documentation of ergm.

```

```
meandeg-ergmTerm Mean vertex degree
```

## Description

This term adds one network statistic to the model equal to the average degree of a node. Note that this term is a constant multiple of both edges and density .

## Usage

\# binary: meandeg

## See Also

ergmTerm for index of model terms currently visible to the package.

```
mm-ergmTerm Mixing matrix cells and margins
```

## Description

attrs is the rows of the mixing matrix and whose RHS gives that for its columns. A one-sided formula (e.g., $\sim \mathrm{A}$ ) is symmetrized (e.g., $\mathrm{A} \sim \mathrm{A}$ ). A two-sided formula with a dot on one side calculates the margins of the mixing matrix, analogously to nodefactor, with A~. calculating the row/sender/b1 margins and.$\sim$ A calculating the column/receiver/b2 margins.

## Usage

\# binary: mm(attrs, levels=NULL, levels2=-1)
\# valued: mm(attrs, levels=NULL, levels2=-1, form="sum")

## Arguments

attrs a two-sided formula whose LHS gives the attribute or attribute function (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.) for the rows of the mixing matrix and whose RHS gives for its columns. A onesided formula (e.g., $\sim A$ ) is symmetrized (e.g., A $\sim A$ )
levels subset of rows and columns to be used. (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)
levels2 which specific cells of the matrix to include
form character how to aggregate tie values in a valued ERGM

```

## Description

In binary ERGMs, equal to the number of pairs of actors $i$ and $j$ for which $(i \rightarrow j)$ and $(j \rightarrow i)$ both exist. For valued ERGMs, equal to $\sum_{i<j} m\left(y_{i, j}, y_{j, i}\right)$, where $m$ is determined by form argument: "min" for $\min \left(y_{i, j}, y_{j, i}\right)$, "nabsdiff" for $-\left|y_{i, j}, y_{j, i}\right|$, "product" for $y_{i, j} y_{j, i}$, and "geometric" for $\sqrt{y_{i, j}} \sqrt{y_{j, i}}$. See Krivitsky (2012) for a discussion of these statistics. form="threshold" simply computes the binary mutuality after thresholding at threshold.
This term can only be used with directed networks.

## Usage

\# binary: mutual(same=NULL, by=NULL, diff=FALSE, keep=NULL, levels=NULL)
\# valued: mutual(form="min", threshold=0)

## Arguments

same if the optional argument is passed (see Specifying Vertex attributes and Levels (?nodal_attributes) for details), only mutual pairs that match on the attribute are counted; separate counts for each unique matching value can be obtained by using diff=TRUE with same. Only one of same or by may be used. If both parameters are used, by is ignored. This paramer is affected by diff.
by if the optional argument is passed (see Specifying Vertex attributes and Levels (?nodal_attributes) for details), then each node is counted separately for each mutual pair in which it occurs and the counts are tabulated by unique values of the attribute. This means that the sum of the mutual statistics when by is used will equal twice the standard mutual statistic. Only one of same or by may be used. If both parameters are used, by is ignored. This paramer is not affected by diff.
keep deprecated
levels which statistics should be kept whenever the mutual term would ordinarily result in multiple statistics. (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)
form character how to aggregate tie values in a valued ERGM

## Note

The argument keep is retained for backwards compatibility and may be removed in a future version. When both keep and levels are passed, levels overrides keep.

## See Also

```
nearsimmelian-ergmTerm
```

## Near simmelian triads

## Description

This term adds one statistic to the model equal to the number of near Simmelian triads, as defined by Krackhardt and Handcock (2007). This is a sub-graph of size three which is exactly one tie short of being complete.

## Usage

\# binary: nearsimmelian

## Note

This term can only be used with directed networks.

## See Also

```
network.list A convenience container for a list of network objects, output by
                    simulate.ergm among others.
```

## Description

A convenience container for a list of network objects, output by simulate. ergm among others.

## Usage

```
network.list(object, ...)
## S3 method for class 'network.list'
print(x, stats.print = FALSE, ...)
## S3 method for class 'network.list'
summary(
        object,
        stats.print = TRUE,
        net.print = FALSE,
        net.summary = FALSE,
)
```

## Arguments

| object, x | a list of networks or a network. list object. |
| :--- | :--- |
| $\ldots$ | for network.list, additional attributes to be set on the network list; for others, <br> arguments passed down to lower-level functions. |
| stats.print | Logical: If TRUE, print network statistics. |
| net.print | Logical: If TRUE, print network overviews. |
| net.summary | Logical: If TRUE, print network summaries. |

## Methods (by generic)

- print: A print() method for network lists.
- summary: A summary () method for network lists.

                MCMC.interval=1000))
print(g.sim)
summary(g.sim)
```

nodal_attributes Specifying nodal attributes and their levels

## Description

This document describes the ways to specify nodal attributes or functions of nodal attributes and which levels for categorical factors to include. For the helper functions to facilitate this, see nodal_attributes-API.

## Usage

$\operatorname{LARGEST}(1, a)$
$\operatorname{SMALLEST}(1, ~ a)$
COLLAPSE_SMALLEST (object, n , into)

## Arguments

object, $1, a, n$, into
COLLAPSE_SMALLEST, LARGEST, and SMALLEST are technically functions but they are generally not called in a standard fashion but rather as a part of an vertex attribute specification or a level specification as described below. The above usage examples are needed to pass R's package checking without warnings; please disregard them, and refer to the sections and examples below instead.

## Specifying nodal attributes

Term nodal attribute arguments, typically called attr, attrs, by, or on are interpreted as follows:
a character string Extract the vertex attribute with this name.
a character vector of length $>1$ Extract the vertex attributes and paste them together, separated by dots if the term expects categorical attributes and (typically) combine into a covariate matrix if it expects quantitative attributes.
a function The function is called on the LHS network and additional arguments to ergm_get_vattr(), expected to return a vector or matrix of appropriate dimension. (Shorter vectors and matrix columns will be recycled as needed.)
a formula The expression on the RHS of the formula is evaluated in an environment of the vertex attributes of the network, expected to return a vector or matrix of appropriate dimension. (Shorter vectors and matrix columns will be recycled as needed.) Within this expression, the network itself accessible as either . or .nw. For example, nodecov(~abs(Grade-mean(Grade))/network.size(.)) would return the absolute difference of each actor's "Grade" attribute from its network-wide mean, divided by the network size.
an AsIs object created by I() Use as is, checking only for correct length and type.
Any of these arguments may also be wrapped in or piped through COLLAPSE_SMALLEST (attr, $n$, into) or, attr \%>\% COLLAPSE_SMALLEST ( $n$, into), a convenience function that will transform the attribute by collapsing the smallest $n$ categories into one, naming it into. Note that into must be of the same type (numeric, character, etc.) as the vertex attribute in question.
The name the nodal attribute receives in the statistic can be overridden by setting a an attr()-style attribute "name".

## Specifying categorical attribute levels and their ordering

For categorical attributes, to select which levels are of interest and their ordering, use the argument levels. Selection of nodes (from the appropriate vector of nodal indices) is likewise handled as the selection of levels, using the argument nodes. These arguments are interpreted as follows:
an expression wrapped in $I$ () Use the given list of levels as is.
a numeric or logical vector Used for indexing of a list of all possible levels (typically, unique values of the attribute) in default older (typically lexicographic), i.e., sort (unique(attr)) [levels]. In particular, levels=TRUE will retain all levels. Negative values exclude. Another special value is LARGEST, which will refer to the most frequent category, so, say, to set such a category as the baseline, pass levels=-LARGEST. In addition, LARGEST( $n$ ) will refer to the $n$ largest categories. SMALLEST works analogously. Note that if there are ties in frequencies, they will be broken arbitrarily. To specify numeric or logical levels literally, wrap in I ().
NULL Retain all possible levels; usually equivalent to passing TRUE.
a character vector Use as is.
a function The function is called on the list of unique values of the attribute, the values of the attribute themselves, and the network itself, depending on its arity. Its return value is interpreted as above.
a formula The expression on the RHS of the formula is evaluated in an environment in which the network itself is accessible as .nw, the list of unique values of the attribute as . or as .levels, and the attribute vector itself as .attr. Its return value is interpreted as above.
a matrix For mixing effects (i.e., level2= arguments), a matrix can be used to select elements of the mixing matrix, either by specifying a logical (TRUE and FALSE) matrix of the same dimension as the mixing matrix to select the corresponding cells or a two-column numeric matrix indicating giving the coordinates of cells to be used.

Note that levels, nodes, and others often have a default that is sensible for the term in question.

## Examples

```
library(magrittr) # for %>%
data(faux.mesa.high)
# Activity by grade with a baseline grade excluded:
summary(faux.mesa.high~nodefactor(~Grade))
# Name overrides:
summary(faux.mesa.high~nodefactor("Form"~Grade)) # Only for terms that don't use the LHS.
summary(faux.mesa.high~nodefactor(~structure(Grade, name="Form")))
# Retain all levels:
summary(faux.mesa.high~nodefactor(~Grade, levels=TRUE)) # or levels=NULL
# Use the largest grade as baseline (also Grade 7):
summary(faux.mesa.high~nodefactor(~Grade, levels=-LARGEST))
# Activity by grade with no baseline smallest two grades (11 and
# 12) collapsed into a new category, labelled 0:
table(faux.mesa.high %v% "Grade")
summary(faux.mesa.high~nodefactor((~Grade) %%% COLLAPSE_SMALLEST(2, 0),
                                    levels=TRUE))
# Mixing between lower and upper grades:
summary(faux.mesa.high~mm(~Grade>=10))
# Mixing between grades 7 and 8 only:
summary(faux.mesa.high~mm("Grade", levels=I(c(7,8))))
# or
summary(faux.mesa.high~mm("Grade", levels=1:2))
# or using levels2 (see ? mm) to filter the combinations of levels,
summary(faux.mesa.high~mm("Grade",
            levels2=~sapply(.levels,
                function(l)
                        l[[1]]%in%c(7,8) && l[[2]]%in%c(7,8))))
# Here are some less complex ways to specify levels2. This is the
# full list of combinations of sexes in an undirected network:
summary(faux.mesa.high~mm("Sex", levels2=TRUE))
# Select only the second combination:
summary(faux.mesa.high~mm("Sex", levels2=2))
# Equivalently,
summary(faux.mesa.high~mm("Sex", levels2=-c(1,3)))
# or
summary(faux.mesa.high~mm("Sex", levels2=c(FALSE,TRUE,FALSE)))
# Select all *but* the second one:
summary(faux.mesa.high~mm("Sex", levels2=-2))
# Select via a mixing matrix: (Network is undirected and
# attributes are the same on both sides, so we can use either M or
# its transpose.)
(M <- matrix(c(FALSE,TRUE,FALSE,FALSE),2,2))
summary(faux.mesa.high~mm("Sex", levels2=M)+mm("Sex", levels2=t(M)))
# Select via an index of a cell:
idx <- cbind(1,2)
```

```
summary(faux.mesa.high~mm("Sex", levels2=idx))
# mm() term allows two-sided attribute formulas with different attributes:
summary(faux.mesa.high~mm(Grade~Race, levels2=TRUE))
# It is possible to have collapsing functions in the formula; note
# the parentheses around "~Race": this is because a formula
# operator (~) has lower precedence than pipe (|>):
summary(faux.mesa.high~mm(Grade~(~Race) %>% COLLAPSE_SMALLEST(3,"BWO"), levels2=TRUE))
# Some terms, such as nodecov(), accept matrices of nodal
# covariates. An certain R quirk means that columns whose
# expressions are not typical variable names have their names
# dropped and need to be adjusted. Consider, for example, the
# linear and quadratic effects of grade:
Grade <- faux.mesa.high %v% "Grade"
colnames(cbind(Grade, Grade^2)) # Second column name missing.
colnames(cbind(Grade, Grade2=Grade^2)) # Can be set manually,
colnames(cbind(Grade, `Grade^2`=Grade^2)) # even to non-variable-names.
colnames(cbind(Grade, Grade^2, deparse.level=2)) # Alternatively, deparse.level=2 forces naming.
rm(Grade)
# Therefore, the nodal attribute names are set as follows:
summary(faux.mesa.high~nodecov(~cbind(Grade, Grade^2))) # column names dropped with a warning
summary(faux.mesa.high~nodecov(~cbind(Grade, Grade2=Grade^2))) # column names set manually
summary(faux.mesa.high~nodecov(~cbind(Grade, Grade^2, deparse.level=2))) # using deparse.level=2
# Activity by grade with a random covariate. Note that setting an attribute "name" gives it a name:
randomcov <- structure(I(rbinom(network.size(faux.mesa.high),1,0.5)), name="random")
summary(faux.mesa.high~nodefactor(I(randomcov)))
```

```
nodecov-ergmTerm Main effect of a covariate
```

## Description

This term adds a single network statistic for each quantitative attribute or matrix column to the model equaling the sum of attr (i) and attr(j) for all edges $(i, j)$ in the network. For categorical attributes, see nodefactor. Note that for directed networks, nodecov equals nodeicov plus nodeocov.

## Usage

\# binary: nodecov(attr)
\# binary: nodemain
\# valued: nodecov(attr, form="sum")
\# valued: nodemain(attr, form="sum")

## Arguments

attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.)
form character how to aggregate tie values in a valued ERGM

## Note

ergm versions 3.9.4 and earlier used different arguments for this term. See ergm-options for how to invoke the old behaviour.

## See Also

ergmTerm for index of model terms currently visible to the package.

$$
\text { nodecovar-ergmTerm } \quad \text { Covariance of undirected dyad values incident on each actor }
$$

## Description

This term adds one statistic equal to $\sum_{i, j<k} y_{i, j} y_{i, k} /(n-2)$. This can be viewed as a valued analog of the star (2) statistic.

## Usage

\# valued: nodecovar(center, transform)

## Arguments

center If center=TRUE , the $y$.,. s are centered by their mean over the whole network before the calculation. Note that this makes the model non-local, but it may alleviate multimodailty.
transform If transform="sqrt", $y$.,. s are repaced by their square roots before the calculation. This makes sense for counts in particular. If center=TRUE as well, they are centered by the mean of the square roots.

## Note

Note that this term replaces nodesqrtcovar, which has been deprecated in favor of nodecovar (transform="sqrt")

## See Also

ergmTerm for index of model terms currently visible to the package.

```
nodefactor-ergmTerm Factor attribute effect
```

## Description

This term adds multiple network statistics to the model, one for each of (a subset of) the unique values of the attr attribute (or each combination of the attributes given). Each of these statistics gives the number of times a node with that attribute or those attributes appears in an edge in the network.

## Usage

\# binary: nodefactor(attr, base=1, levels=-1)
\# valued: nodefactor(attr, base=1, levels=-1, form="sum")

## Arguments

| attr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) |
| :--- | :--- |
| base | deprecated |
| levels | this optional argument controls which levels of the attribute attributes and Levels <br> (?nodal_attributes) for details.) <br> character how to aggregate tie values in a valued ERGM |
| form | chat |

## Note

To include all attribute values is usually not a good idea, because the sum of all such statistics equals the number of edges and hence a linear dependency would arise in any model also including edges. The default, levels=-1, is therefore to omit the first (in lexicographic order) attribute level. To include all levels, pass either levels=TRUE (i.e., keep all levels) or levels=NULL (i.e., do not filter levels).

The argument base is retained for backwards compatibility and may be removed in a future version. When both base and levels are passed, levels overrides base.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
    nodeicov-ergmTerm Main effect of a covariate for in-edges
```

## Description

This term adds a single network statistic for each quantitative attribute or matrix column to the model equaling the total value of attr( $j$ ) for all edges $(i, j)$ in the network. This term may only be used with directed networks. For categorical attributes, see nodeifactor .

## Usage

\# binary: nodeicov(attr)
\# valued: nodeicov(attr, form="sum")

## Arguments

$\begin{array}{ll}\text { attr } & \begin{array}{l}\text { quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) } \\ \text { for details.) }\end{array} \\ \text { form } & \text { character how to aggregate tie values in a valued ERGM }\end{array}$

## Note

ergm versions 3.9.4 and earlier used different arguments for this term. See ergm-options for how to invoke the old behaviour.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
nodeicovar-ergmTerm Covariance of in-dyad values incident on each actor
```

## Description

This term adds one statistic equal to $\sum_{i, j, k} y_{j, i} y_{k, i} /(n-2)$. This can be viewed as a valued analog of the istar (2) statistic.

## Usage

\# valued: nodeicovar(center, transform)

## Arguments

center If center=TRUE , the $y .$, s are centered by their mean over the whole network before the calculation. Note that this makes the model non-local, but it may alleviate multimodailty.
transform If transform="sqrt", $y$.,. s are repaced by their square roots before the calculation. This makes sense for counts in particular. If center=TRUE as well, they are centered by the mean of the square roots.

## Note

Note that this term replaces nodeisqrtcovar, which has been deprecated in favor of nodeicovar (transform="sqrt")

## See Also

ergmTerm for index of model terms currently visible to the package.

```
nodeifactor-ergmTerm Factor attribute effect for in-edges
```

## Description

This term adds multiple network statistics to the model, one for each of (a subset of) the unique values of the attr attribute (or each combination of the attributes given). Each of these statistics gives the number of times a node with that attribute or those attributes appears as the terminal node of a directed tie.

For an analogous term for quantitative vertex attributes, see nodeicov.

## Usage

\# binary: nodeifactor(attr, base=1, levels=-1)
\# valued: nodeifactor(attr, base=1, levels=-1, form="sum")

## Arguments

attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.)
base deprecated
levels this optional argument controls which levels of the attribute attributes and Levels (?nodal_attributes) for details.)
form character how to aggregate tie values in a valued ERGM

## Note

To include all attribute values is usually not a good idea, because the sum of all such statistics equals the number of edges and hence a linear dependency would arise in any model also including edges. The default, levels $=-1$, is therefore to omit the first (in lexicographic order) attribute level. To include all levels, pass either levels=TRUE (i.e., keep all levels) or levels=NULL (i.e., do not filter levels).
The argument base is retained for backwards compatibility and may be removed in a future version. When both base and levels are passed, levels overrides base.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
nodematch-ergmTerm Uniform homophily and differential homophily
```

## Description

When diff=FALSE, this term adds one network statistic to the model, which counts the number of edges $(i, j)$ for which $\operatorname{attr}(\mathrm{i})==a t \operatorname{tr}(\mathrm{j})$. This is also called "uniform homophily," because each group is assumed to have the same propensity for within-group ties. When multiple attribute names are given, the statistic counts only ties for which all of the attributes match. When diff=TRUE, $p$ network statistics are added to the model, where $p$ is the number of unique values of the attr attribute. The $k$ th such statistic counts the number of edges $(i, j)$ for which attr $(i)==\operatorname{attr}(j)$ $==$ value(k), where value $(\mathrm{k})$ is the $k$ th smallest unique value of the attr attribute. This is also called "differential homophily," because each group is allowed to have a unique propensity for within-group ties. Note that a statistical test of uniform vs. differential homophily should be conducted using the ANOVA function.
By default, matches on all levels $k$ are counted. This works for both diff=TRUE and diff=FALSE .

## Usage

\# binary: nodematch(attr, diff=FALSE, keep=NULL, levels=NULL)
\# valued: nodematch(attr, diff=FALSE, keep=NULL, levels=NULL, form="sum")
\# valued: match(attr, diff=FALSE, keep=NULL, levels=NULL, form="sum")

## Arguments

| attr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) |
| :--- | :--- |
| diff | specify if the term has uniform or differential homophily <br> keep <br> deprecated |
| levels | this optional argument controls which levels of the attribute attributes and Levels <br> (?nodal_attributes) for details.) <br> character how to aggregate tie values in a valued ERGM |

## Note

The argument keep is retained for backwards compatibility and may be removed in a future version. When both keep and levels are passed, levels overrides keep.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
NodematchFilter-ergmTerm
```

Filtering on nodematch

## Description

Evaluates the terms specified in formula on a network constructed by taking $y$ and removing any edges for which attrname (i)!=attrname ( $j$ ).

## Usage

\# binary: NodematchFilter(formula, attrname)

## Arguments

| formula | formula to be evaluated |
| :--- | :--- |
| attrname | a character vector giving one or more names of attributes in the network's vertex <br> attribute list. |

## See Also

ergmTerm for index of model terms currently visible to the package.

```
nodemix-ergmTerm Nodal attribute mixing
```

## Description

By default, this term adds one network statistic to the model for each possible pairing of attribute values. The statistic equals the number of edges in the network in which the nodes have that pairing of values. (When multiple attributes are specified, a statistic is added for each combination of attribute values for those attributes.) In other words, this term produces one statistic for every entry in the mixing matrix for the attribute(s). By default, the ordering of the attribute values is lexicographic: alphabetical (for nominal categories) or numerical (for ordered categories).

## Usage

```
\# binary: nodemix(attr, base=NULL, b1levels=NULL, b2levels=NULL, levels=NULL, levels2=-1)
    \# valued: nodemix(attr, base=NULL, b1levels=NULL, b2levels=NULL, levels=NULL,
    \#
        levels2=-1, form="sum")
```

## Arguments

| attr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) <br> deprecated |
| :--- | :--- |
| base |  |

## Note

The argument base is retained for backwards compatibility and may be removed in a future version. When both base and levels are passed, levels overrides base.
The argument base is retained for backwards compatibility and may be removed in a future version. When both base and levels2 are passed, levels2 overrides base.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
nodeocov-ergmTerm Main effect of a covariate for out-edges
```

## Description

This term adds a single network statistic for each quantitative attribute or matrix column to the model equaling the total value of $\operatorname{attr}(i)$ for all edges $(i, j)$ in the network. This term may only be used with directed networks. For categorical attributes, see nodeofactor .
nodeocovar-ergmTerm

## Usage

\# binary: nodeocov(attr)
\# valued: nodeocov(attr, form="sum")

## Arguments

attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.)
form character how to aggregate tie values in a valued ERGM

## Note

ergm versions 3.9.4 and earlier used different arguments for this term. See ergm-options for how to invoke the old behaviour.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
nodeocovar-ergmTerm Covariance of out-dyad values incident on each actor
```

## Description

This term adds one statistic equal to $\sum_{i, j, k} y_{i, j} y_{i, k} /(n-2)$. This can be viewed as a valued analog of the ostar (2) statistic.

## Usage

\# valued: nodeocovar(center, transform)

## Arguments

center whether the $y$.,. s are centered by their mean over the whole network before the calculation. Note that this makes the model non-local, but it may alleviate multimodailty.
transform if transform="sqrt", $y .$, s are repaced by their square roots before the calculation. This makes sense for counts in particular. If center=TRUE as well, they are centered by the mean of the square roots.

## Note

Note that this term replaces nodeosqrtcovar, which has been deprecated in favor of nodeocovar (transform="sqrt")

## See Also

ergmTerm for index of model terms currently visible to the package.

```
nodeofactor-ergmTerm Factor attribute effect for out-edges
```

## Description

This term adds multiple network statistics to the model, one for each of (a subset of) the unique values of the attr attribute (or each combination of the attributes given). Each of these statistics gives the number of times a node with that attribute or those attributes appears as the node of origin of a directed tie.

## Usage

\# binary: nodeofactor(attr, base=1, levels=-1)
\# valued: nodeofactor(attr, base=1, levels=-1, form="sum")

## Arguments

attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.)
base deprecated
levels this optional argument controls which levels of the attribute attributes and Levels (?nodal_attributes) for details.)
form character how to aggregate tie values in a valued ERGM

## Note

The argument base is retained for backwards compatibility and may be removed in a future version. When both base and levels are passed, levels overrides base.
To include all attribute values is usually not a good idea, because the sum of all such statistics equals the number of edges and hence a linear dependency would arise in any model also including edges. The default, levels $=-1$, is therefore to omit the first (in lexicographic order) attribute level. To include all levels, pass either levels=TRUE (i.e., keep all levels) or levels=NULL (i.e., do not filter levels).
This term can only be used with directed networks.

## See Also

ergmTerm for index of model terms currently visible to the package.
nparam Length of the parameter vector associated with an object or with its terms.

## Description

This is a generic that returns the number of parameters associated with a model or a model fit.

## Usage

nparam(object, ...)
\#\# Default S3 method:
nparam(object, ...)
\#\# S3 method for class 'ergm'
nparam(object, offset = NA, ...)

## Arguments

$$
\begin{array}{ll}
\text { object } & \text { An object for which number of parameters is defined. } \\
\ldots & \text { Additional arguments to methods. } \\
\text { offset } & \text { If NA (the default), all model terms are counted; if TRUE, only offset terms are } \\
\text { counted; and if FALSE, offset terms are skipped. }
\end{array}
$$

## Methods (by class)

- default: By default, the length of the coef() vector is returned.
- ergm: A method to return the number of parameters of an ergm fit.
nsp-ergmTerm Nonedgewise shared partners

## Description

This is just like the dsp and esp terms, except this term adds one network statistic to the model for each element in d where the $i$ th such statistic equals the number of non-edges (that is, dyads that do not have an edge) in the network with exactly $d[i]$ shared partners. This term can be used with directed and undirected networks.

## Usage

\# binary: nsp(d)

## Arguments

d
a vector of distinct integers

## Note

For directed networks, only outgoing two-path ("OTP") shared partners are counted. In other words, for a (directed) non-edge ( $i, j$ ) in a directed graph, the number of shared partners counted by nsp is the number of nodes $k$ that have edges $i->k->j$. (These may also be called homogeneous shared partners.) To count other types of shared partners instead, see dnsp.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
observed-ergmConstraint
```

Preserve the observed dyads of the given network

## Description

Preserve the observed dyads of the given network.

## Usage

\# observed

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

```
odegrange-ergmTerm Out-degree range
```

## Description

This term adds one network statistic to the model for each element of from (or to ); the $i$ th such statistic equals the number of nodes in the network of out-degree greater than or equal to from[i] but strictly less than to[i], i.e. with out-edge count in semiopen interval [from, to) .
This term can only be used with directed networks; for undirected networks (bipartite and not) see degrange. For degrees of specific modes of bipartite networks, see b1degrange and b2degrange . For in-degrees, see idegrange .

## Usage

\# binary: odegrange(from, to=+Inf, by=NULL, homophily=FALSE, levels=NULL)

## Arguments

from, to vectors of distinct integers. If one of the vectors have length 1 , it is recycled to the length of the other. Otherwise, it must have the same length.
by, homophily the optional argument by specifies a vertex attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details). If this is specified and homophily is TRUE, then degrees are calculated using the subnetwork consisting of only edges whose endpoints have the same value of the by attribute. If by is specified and homophily is FALSE (the default), then separate degree range statistics are calculated for nodes having each separate value of the attribute.
levels TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)
attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.)

## See Also

ergmTerm for index of model terms currently visible to the package.

```
odegree-ergmTerm Out-degree
```

## Description

This term adds one network statistic to the model for each element in d ; the $i$ th such statistic equals the number of nodes in the network of out-degree $d[i]$, i.e. the number of nodes with exactly $d[i]$ out-edges. This term can only be used with directed networks; for undirected networks see degree

## Usage

\# binary: odegree(d, by=NULL, homophily=FALSE, levels=NULL)

## Arguments

d
a vector of distinct integers
by, homophily the optional argument by specifies a vertex attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details). If this is specified and homophily is TRUE, then degrees are calculated using the subnetwork consisting of only edges whose endpoints have the same value of the by attribute. If by is specified and homophily is FALSE (the default), then separate degree range statistics are calculated for nodes having each separate value of the attribute.
levels TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

This term adds one network statistic to the model equaling the sum over the actors of each actor's outdegree taken to the $3 / 2$ power (or, equivalently, multiplied by its square root). This term is analogous to the term of Snijders et al. (2010), equation (12). This term can only be used with directed networks.

## Usage

\# binary: odegree1.5

## See Also

ergmTerm for index of model terms currently visible to the package.

```
odegreedist-ergmConstraint
```

Preserve the outdegree distribution

## Description

Preserve the outdegree distribution of the given network.

## Usage

\# odegreedist

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

```
odegrees-ergmConstraint
```

Preserve outdegree for directed networks

## Description

For directed networks, preserve the outdegree of each vertex of the given network, while allowing indegree to vary

## Usage

\# odegrees

## See Also

ergmConstraint for index of constraints and hints currently visible to the package.

$$
\text { Offset-ergmTerm } \quad \text { Terms with fixed coefficients }
$$

## Description

This operator is analogous to the offset () wrapper, but the coefficients are specified within the term and the curved ERGM mechanism is used internally.

## Usage

\# binary: Offset(formula, coef, which)

## Arguments

formula a one-sided ergm()-style formula with the terms to be evaluated
coef coefficients to the formula
which used to specify which of the parameters in the formula are fixed. It can be a logical vector (recycled as needed), a numeric vector of indices of parameters to be fixed, or a character vector of parameter names.

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

This term adds one statistic to the model equal to the number of 2 -stars minus three times the number of triangles in the network. It is currently only implemented for undirected networks.

## Usage

\# binary: opentriad

## See Also

ergmTerm for index of model terms currently visible to the package.

```
ostar-ergmTerm k-Outstars
```

## Description

This term adds one network statistic to the model for each element in k . The $i$ th such statistic counts the number of distinct k[i] -outstars in the network, where a $k$-outstar is defined to be a node $N$ and a set of $k$ different nodes $\left\{O_{1}, \ldots, O_{k}\right\}$ such that the ties $\left(N \rightarrow O_{j}\right)$ exist for $j=1, \ldots, k$. If attr is specified then the count is the number of $k$-outstars where all nodes have the same value of the attribute. This term can only be used with directed networks; for undirected networks see kstar

## Usage

\# binary: ostar(k, attr=NULL, levels=NULL)

## Arguments

| $k$ | a vector of distinct integers |
| :--- | :--- |
| attr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) <br> for details.) |
| levels | TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for <br> details.) |

Note
ostar(1) is equal to both istar(1) and edges.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
    param_names Names of the parameters associated with an object.
```

## Description

This is a generic that returns a vector giving the names of the parameters associated with a model or a model fit.

## Usage

param_names(object, ...)
\#\# Default S3 method:
param_names(object, ...)

## Arguments

object An object for which parameter names are defined.
... Additional arguments to methods.

## Methods (by class)

- default: By default, the names of the coef() vector is returned.

```
predict.formula ERGM-based tie probabilities
```

## Description

Calculate model-predicted conditional and unconditional tie probabilities for dyads in the given network. Conditional probabilities of a dyad given the state of all the remaining dyads in the graph are computed exactly. Unconditional probabilities are computed through simulating networks using the given model. Currently there are two methods implemented:

- Method for formula objects requires (1) an ERGM model formula with an existing network object on the left hand side and model terms on the right hand side, and (2) a vector of corresponding parameter values.
- Method for ergm objects, as returned by ergm(), takes both the formula and parameter values from the fitted model object.

Both methods can limit calculations to specific set of dyads of interest.

## Usage

```
## S3 method for class 'formula'
predict(
    object,
    theta,
    conditional = TRUE,
    type = c("response", "link"),
    nsim = 100,
    output = c("data.frame", "matrix"),
    ...
)
## S3 method for class 'ergm'
predict(object, ...)
```

## Arguments

| object | a formula or a fitted ERGM model object |
| :--- | :--- |
| theta | numeric vector of ERGM model parameter values |
| conditional | logical whether to compute conditional or unconditional predicted probabilities <br> character element, one of "response" (default) or "link" - whether the re- <br> turned predictions are on the probability scale or on the scale of linear predictor. <br> This is similar to type argument of predict.glm(). <br> integer, number of simulated networks used for computing unconditional prob- <br> abilities. Defaults to 100. <br> character, type of object returned. Defaults to "data. frame". See section Value <br> below. |
| output | other arguments passed to/from other methods. For the predict.formula method, <br> if conditional=TRUE arguments are passed to ergmMPLE(). If conditional=FALSE <br> arguments are passed to simulate_formula(). |
| . |  |

## Value

Type of object returned depends on the argument output. If output="data.frame" the function will return a data frame with columns:

- tail, head - indices of nodes identifying a dyad
- p - predicted conditional tie probability

If output="matrix" the function will return an "adjacency matrix" with the predicted probabilities. Diagonal values are 0s.

## Examples

```
# A three-node empty directed network
net <- network.initialize(3, directed=TRUE)
```

```
# In homogeneous Bernoulli model with odds of a tie of 1/5 all ties are
# equally likely
predict(net ~ edges, log(1/5))
# Let's add a tie so that 'net` has 1 tie out of possible 6 (so odds of 1/5)
net[1,2] <- 1
# Fit the model
fit <- ergm(net ~ edges)
# The p's should be identical
predict(fit)
```

Prod-ergmTerm
A product (or an arbitrary power combination) of one or more formu-
las

## Description

This operator evaluates a list of formulas whose corresponnding RHS statistics will be multiplied elementwise. They are required to be nonnegative.

## Usage

\# binary: Prod(formulas, label)
\# valued: Prod(formulas, label)

## Arguments

formulas a list (constructed using list() or c()) of ergm()-style formulas whose RHS gives the statistics to be evaluated, or a single formula.
If a formula in the list has an LHS, it is interpreted as follows:

- a numeric scalar: Network statistics of this formula will be exponentiated by this.
- a numeric vector: Corresponding network statistics of this formula will be exponentiated by this.
- a numeric matrix: Vector of network statistics will be exponentiated by this using the same pattern as matrix multiplication.
- a character string: One of several predefined multiplicative combinations. Currently supported presets are as follows:
- "prod": Network statistics of this formula will be multiplied together; equivalent to matrix $(1,1, p)$, where $p$ is the length of the network statistic vector.
- "geomean": Network statistics of this formula will be geometrically averaged; equivalent to matrix $(1 / p, 1, p)$, where $p$ is the length of the network statistic vector.

label | used to specify the names of the elements of the resulting term product vector. If |
| :--- |
| label is a character vector of length 1 , it will be recycled with indices appended. |
| If a function is specified, formulas parameter names are extracted and their list |
| of character vectors is passed label. |

## Details

Note that each formula must either produce the same number of statistics or be mapped through a matrix to produce the same number of statistics.
A single formula is also permitted. This can be useful if one wishes to, say, scale or multiply together the statistics returned by a formula.
Offsets are ignored unless there is only one formula and the transformation only scales the statistics (i.e., the effective transformation matrix is diagonal).

Curved models are supported, subject to some limitations. In particular, the first model's etamap will be used, overwriting the others. If label is not of length 1 , it should have an attr -style attribute "curved" specifying the names for the curved parameters.

## Note

The current implementation piggybacks on the Log, Exp, and Sum operators, essentially Exp( $\sim \operatorname{Sum}(\sim \log (f o r m u l a)$, label)). This may result in loss of precision, particularly for extremely large or small statistics. The implementation may change in the future.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
rank_test.ergm A lack-of-fit test for ERGMs
```

## Description

A simple test reporting the sample quantile of the observed network's probability in the distribution under the MLE. This is a conservative p-value for the null hypothesis of the observed network being a draw from the distribution of interest.

## Usage

rank_test.ergm(x, plot = FALSE)

## Arguments

X
an ergm() object.
plot if TRUE, plot the empirical distribution.

## Value

The sample quantile of the observed network's probability among the predicted.

```
receiver-ergmTerm Receiver effect
```

## Description

This term adds one network statistic for each node equal to the number of in-ties for that node. This measures the popularity of the node. The term for the first node is omitted by default because of linear dependence that arises if this term is used together with edges, but its coefficient can be computed as the negative of the sum of the coefficients of all the other actors. That is, the average coefficient is zero, following the Holland-Leinhardt parametrization of the \$p_1\$ model (Holland and Leinhardt, 1981). This term can only be used with directed networks. For undirected networks, see sociality.

## Usage

\# binary: receiver(base=1, nodes=-1)
\# valued: receiver(base=1, nodes=-1, form="sum")

## Arguments

| base | deprecated |
| :--- | :--- |
| nodes | specify which nodes' statistics should be included or excluded (see Specifying <br> Vertex attributes and Levels (?nodal_attributes) for details) <br> character how to aggregate tie values in a valued ERGM |
| form | chat |

## Note

The argument base is retained for backwards compatibility and may be removed in a future version. When both base and nodes are passed, nodes overrides base.

## See Also

ergmTerm for index of model terms currently visible to the package.
S-ergmTerm Evaluation on an induced subgraph

## Description

This operator takes a two-sided forumla attrs whose LHS gives the attribute or attribute function for which tails and heads will be used to construct the induced subgraph. They must evaluate either to a logical vector equal in length to the number of tails (for LHS) and heads (for RHS) indicating which nodes are to be used to induce the subgraph or a numeric vector giving their indices.

## Usage

\# binary: S(formula, attrs)

## Arguments

formula a one-sided ergm()-style formula with the terms to be evaluated
attrs a two-sided formula to be used. A one-sided formula (e.g., $\sim \mathrm{A}$ ) is symmetrized (e.g., A~A ).

## Details

As with indexing vectors, the logical vector will be recycled to the size of the network or the size of the appropriate bipartition, and negative indices will deselect vertices.

When the two sets are identical, the induced subgraph retains the directedness of the original graph. Otherwise, an undirected bipartite graph is induced.

samplk $\quad$| Longitudinal networks of positive affection within a monastery as a |
| :--- |
| "network" object |

## Description

Three network objects containing the "liking" nominations of Sampson's (1969) monks at the three time points.

## Usage

data(samplk)

## Details

Sampson (1969) recorded the social interactions among a group of monks while he was a resident as an experimenter at the cloister. During his stay, a political "crisis in the cloister" resulted in the expulsion of four monks- namely, the three "outcasts," Brothers Elias, Simplicius, Basil, and the leader of the "young Turks," Brother Gregory. Not long after Brother Gregory departed, all but one of the "young Turks" left voluntarily: Brothers John Bosco, Albert, Boniface, Hugh, and Mark. Then, all three of the "waverers" also left: First, Brothers Amand and Victor, then later Brother Romuald. Eventually, Brother Peter and Brother Winfrid also left, leaving only four of the original group.

Of particular interest are the data on positive affect relations ("liking," using the terminology later adopted by White et al. (1976)), in which each monk was asked if he had positive relations to each of the other monks. Each monk ranked only his top three choices (or four, in the case of ties) on
"liking". Here, we consider a directed edge from monk A to monk B to exist if A nominated B among these top choices.
The data were gathered at three times to capture changes in group sentiment over time. They represent three time points in the period during which a new cohort had entered the monastery near the end of the study but before the major conflict began. These three time points are labeled T2, T3, and T4 in Tables D5 through D16 in the appendices of Sampson's 1969 dissertation. and the corresponding network data sets are named samplk1, samplk2, and samplk3, respectively.
See also the data set sampson containing the time-aggregated graph samplike.
samplk3 is a data set of Hoff, Raftery and Handcock (2002).
The data sets are stored as network objects with three vertex attributes:
group Groups of novices as classified by Sampson, that is, "Loyal", "Outcasts", and "Turks", but with a fourth group called the "Waverers" by White et al. (1975) that comprises two of the original Loyal opposition and one of the original Outcasts. See the samplike data set for the original classifications of these three waverers.
cloisterville An indicator of attendance in the minor seminary of "Cloisterville" before coming to the monastery.
vertex.names The given names of the novices. NB: These names have been corrected as of ergm version 3.6.1.

This data set is standard in the social network analysis literature, having been modeled by Holland and Leinhardt (1981), Reitz (1982), Holland, Laskey and Leinhardt (1983), Fienberg, Meyer, and Wasserman (1981), and Hoff, Raftery, and Handcock (2002), among others. This is only a small piece of the data collected by Sampson.
This data set was updated for version 2.5 (March 2012) to add the cloisterville variable and refine the names. This information is from de Nooy, Mrvar, and Batagelj (2005). The original vertex names were: Romul_10, Bonaven_5, Ambrose_9, Berth_6, Peter_4, Louis_11, Victor_8, Winf_12, John_1, Greg_2, Hugh_14, Boni_15, Mark_7, Albert_16, Amand_13, Basil_3, Elias_17, Simp_18. The numbers indicate the ordering used in the original dissertation of Sampson (1969).

## Mislabeling in Versions Prior to 3.6.1

In ergm versions 3.6.0 and earlier, The adjacency matrices of the samplike, samplk1, samplk2, and samplk3 networks reflected the original Sampson (1969) ordering of the names even though the vertex labels used the name order of de Nooy, Mrvar, and Batagelj (2005). That is, in ergm version 3.6.0 and earlier, the vertices were mislabeled. The correct order is the same one given in Tables D5, D9, and D13 of Sampson (1969): John Bosco, Gregory, Basil, Peter, Bonaventure, Berthold, Mark, Victor, Ambrose, Romauld (Sampson uses both spellings "Romauld" and "Ramauld" in the dissertation), Louis, Winfrid, Amand, Hugh, Boniface, Albert, Elias, Simplicius. By contrast, the order given in ergm version 3.6.0 and earlier is: Ramuald, Bonaventure, Ambrose, Berthold, Peter, Louis, Victor, Winfrid, John Bosco, Gregory, Hugh, Boniface, Mark, Albert, Amand, Basil, Elias, Simplicius.

| sampson | Cumulative network of positive affection within a monastery as a "net- <br> work" object |
| :--- | :--- |

## Description

A network object containing the cumulative "liking" nominations of Sampson's (1969) monks over the three time points.

## Usage <br> data(sampson)

## Details

Sampson (1969) recorded the social interactions among a group of monks while he was a resident as an experimenter at the cloister. During his stay, a political "crisis in the cloister" resulted in the expulsion of four monks- namely, the three "outcasts," Brothers Elias, Simplicius, Basil, and the leader of the "young Turks," Brother Gregory. Not long after Brother Gregory departed, all but one of the "young Turks" left voluntarily: Brothers John Bosco, Albert, Boniface, Hugh, and Mark. Then, all three of the "waverers" also left: First, Brothers Amand and Victor, then later Brother Romuald. Eventually, Brother Peter and Brother Winfrid also left, leaving only four of the original group.
Of particular interest are the data on positive affect relations ("liking," using the terminology later adopted by White et al. (1976)), in which each monk was asked if he had positive relations to each of the other monks. Each monk ranked only his top three choices (or four, in the case of ties) on "liking". Here, we consider a directed edge from monk A to monk B to exist if A nominated B among these top choices.
The data were gathered at three times to capture changes in group sentiment over time. They represent three time points in the period during which a new cohort had entered the monastery near the end of the study but before the major conflict began. These three time points are labeled T2, T3, and T4 in Tables D5 through D16 in the appendices of Sampson's 1969 dissertation. The samplike data set is the time-aggregated network. Thus, a tie from monk A to monk B exists if A nominated $B$ as one of his three (or four, in case of ties) best friends at any of the three time points.
See also the data sets samplk1, samplk2, and samplk3, containing the networks at each of the three individual time points.
The data set is stored as a network object with three vertex attributes:
group Groups of novices as classified by Sampson: "Loyal", "Outcasts", and "Turks".
cloisterville An indicator of attendance in the minor seminary of "Cloisterville" before coming to the monastery.
vertex.names The given names of the novices. NB: These names have been corrected as of ergm version 3.6.1; see details below.

In addition, the data set has an edge attribute, nominations, giving the number of times (out of 3) that monk A nominated monk B.

This data set is standard in the social network analysis literature, having been modeled by Holland and Leinhardt (1981), Reitz (1982), Holland, Laskey and Leinhardt (1983), Fienberg, Meyer, and Wasserman (1981), and Hoff, Raftery, and Handcock (2002), among others. This is only a small piece of the data collected by Sampson.
This data set was updated for version 2.5 (March 2012) to add the cloisterville variable and refine the names. This information is from de Nooy, Mrvar, and Batagelj (2005). The original vertex names were: Romul_10, Bonaven_5, Ambrose_9, Berth_6, Peter_4, Louis_11, Victor_8, Winf_12, John_1, Greg_2, Hugh_14, Boni_15, Mark_7, Albert_16, Amand_13, Basil_3, Elias_17, Simp_18. The numbers indicate the ordering used in the original dissertation of Sampson (1969).

## Mislabeling in Versions Prior to 3.6.1

In ergm version 3.6.0 and earlier, The adjacency matrices of the samplike, samplk1, samplk2, and samplk3 networks reflected the original Sampson (1969) ordering of the names even though the vertex labels used the name order of de Nooy, Mrvar, and Batagelj (2005). That is, in ergm version 3.6.0 and earlier, the vertices were mislabeled. The correct order is the same one given in Tables D5, D9, and D13 of Sampson (1969): John Bosco, Gregory, Basil, Peter, Bonaventure, Berthold, Mark, Victor, Ambrose, Romauld (Sampson uses both spellings "Romauld" and "Ramauld" in the dissertation), Louis, Winfrid, Amand, Hugh, Boniface, Albert, Elias, Simplicius. By contrast, the order given in ergm version 3.6.0 and earlier is: Ramuald, Bonaventure, Ambrose, Berthold, Peter, Louis, Victor, Winfrid, John Bosco, Gregory, Hugh, Boniface, Mark, Albert, Amand, Basil, Elias, Simplicius.

san | Use Simulated Annealing to attempt to match a network to a vector of |
| :--- |
| mean statistics |

## Description

This function attempts to find a network or networks whose statistics match those passed in via the target.stats vector.

## Usage

```
san(object, ...)
## S3 method for class 'formula'
san(
    object,
    response = NULL,
    reference = ~Bernoulli,
    constraints = ~.,
    target.stats = NULL,
    nsim = NULL,
    basis = NULL,
    output = c("network", "edgelist", "ergm_state"),
    only.last = TRUE,
    control = control.san(),
    verbose = FALSE,
    offset.coef = NULL,
)
## S3 method for class 'ergm_model'
san(
    object,
    reference = ~Bernoulli,
    constraints = ~.,
    target.stats = NULL,
    nsim = NULL,
    basis = NULL,
    output = c("network", "edgelist", "ergm_state"),
    only.last = TRUE,
    control = control.san(),
    verbose = FALSE,
    offset.coef = NULL,
)
```

## Arguments

object Either a formula or an ergm object. The formula should be of the form y ~ <model terms>, where $y$ is a network object or a matrix that can be coerced to a network object. For the details on the possible <model terms>, see ergmTerm. To create a network object in, use the network() function, then add nodal attributes to it using the \%v\% operator if necessary.
Further arguments passed to other functions.
response Either a character string, a formula, or NULL (the default), to specify the response attributes and whether the ERGM is binary or valued. Interpreted as follows:

NULL Model simple presence or absence, via a binary ERGM.
character string The name of the edge attribute whose value is to be modeled. Type of ERGM will be determined by whether the attribute is logical (TRUE/FALSE) for binary or numeric for valued.
a formula must be of the form NAME~EXPR|TYPE (with \| being literal). EXPR is evaluated in the formula's environment with the network's edge attributes accessible as variables. The optional NAME specifies the name of the edge attribute into which the results should be stored, with the default being a concise version of EXPR. Normally, the type of ERGM is determined by whether the result of evaluating EXPR is logical or numeric, but the optional TYPE can be used to override by specifying a scalar of the type involved (e.g., TRUE for binary and 1 for valued).
reference A one-sided formula specifying the reference measure $(h(y)$ ) to be used. See help for ERGM reference measures implemented in the ergm package.
constraints A one-sided formula specifying one or more constraints on the support of the distribution of the networks being simulated. See the documentation for a similar argument for ergm and see list of implemented constraints for more information. For simulate.formula, defaults to no constraints. For simulate.ergm, defaults to using the same constraints as those with which object was fitted.
target.stats A vector of the same length as the number of non-offset statistics implied by the formula, which is either object itself in the case of san. formula or object\$formula in the case of san. ergm.
nsim Number of networks to generate. Deprecated: just use replicate().
basis If not NULL, a network object used to start the Markov chain. If NULL, this is taken to be the network named in the formula.
output Character, one of "network" (default), "edgelist", or "ergm_state": determines the output format. Partial matching is performed.
only.last if TRUE, only return the last network generated; otherwise, return a network. list with nsim networks.
control A list of control parameters for algorithm tuning, typically constructed with control.san(). Its documentation gives the the list of recognized control parameters and their meaning. The more generic utility snctrl() (StatNet ConTRoL) also provides argument completion for the available control functions and limited argument name checking.

| verbose | A logical or an integer to control the amount of progress and diagnostic in- <br> formation to be printed. FALSE/0 produces minimal output, wit higher values <br> producing more detail. Note that very high values (5+) may significantly slow <br> down processing. |
| :--- | :--- |
| offset.coef | A vector of offset coefficients; these must be passed in by the user. Note that <br> these should be the same set of coefficients one would pass to ergm via its <br> offset.coef argument. |
| formula | (By default, the formula is taken from the ergm object. If a different formula <br> object is wanted, specify it here. |

## Details

Acceptance probabilities for proposed toggles are computed as we now describe. There are two contributions: one from targeted statistics and one from offsets.

For the targeted statistics, a matrix of weights $W$ is determined on each san iteration as follows. On the first iteration, the matrix $W$ is the $n$ by $n$ identity matrix ( $\mathrm{n}=$ number of target statistics), divided by $n$. On subsequent iterations: if control\$SAN.invcov.diag = FALSE (the default), then the matrix $W$ is the inverse of the covariance matrix of the targeted statistics, divided by the sum of its (the inverse's) diagonal; if control\$SAN.invcov.diag = TRUE, then $W$ is the inverse of the diagonal (regarded as a matrix) of the covariance matrix of the targeted statistics, divided by the sum of its (the inverse's) diagonal. In either of these two cases, the covariance matrix is computed based on proposals (not acceptances) made on the previous iteration, and the normalization for $W$ is such that $\operatorname{sum}(\operatorname{diag}(W))=1$. The component of the acceptance probability coming from the targeted statistics is then computed for a given $W$ as $\exp ([y . W y-x . W x] / T)$ where $T$ is the temperature, $y$ the column vector of differences network statistics - target statistics computed before the current proposal is made, $x$ the column vector of differences network statistics - target statistics computed assuming the current proposal is accepted, and . the dot product. If control\$SAN. maxit $>1$, then on the $i$ th iteration, the temperature T takes the value control\$SAN.tau * (1/i-1/control\$SAN.maxit)/(1-1/control\$SAN.maxit); if control\$SAN.maxit $=1$, then the temperature $T$ takes the value 0 . Thus, $T$ steps down from control\$SAN. tau to 0 and is always 0 on the final iteration.

Offsets also contribute to the acceptance probability, as follows. If eta are the canonical offsets and Delta the corresponding change statistics for a given proposal, then the offset contribution to the acceptance probability is simply $\exp$ (eta.Delta) where . denotes the dot product. By default, finite offsets are ignored, but this behavior can be changed by setting control $\$$ SAN. ignore.finite.offsets = FALSE.

The overall acceptance probability is the product of the targeted statistics contribution and the offset contribution (with the product capped at one).

## Value

A network or list of networks that hopefully have network statistics close to the target. stats vector. Additionally, attr()-style attributes formula and stats are included.

## Methods (by class)

- formula: Sufficient statistics are specified by a formula.
- ergm_model: A lower-level function that expects a pre-initialized ergm_model.

## Examples

```
# initialize x to a random undirected network with 50 nodes and a density of 0.1
x <- network(50, density = 0.05, directed = FALSE)
# try to find a network on }50\mathrm{ nodes with 300 edges, }150\mathrm{ triangles,
# and 1250 4-cycles, starting from the network x
y <- san(x ~ edges + triangles + cycle(4), target.stats = c(300, 150, 1250))
# check results
summary(y ~ edges + triangles + cycle(4))
# initialize x to a random directed network with 50 nodes
x <- network(50)
# add vertex attributes
x %v% 'give' <- runif(50, 0, 1)
x %v% 'take' <- runif(50, 0, 1)
# try to find a set of 100 directed edges making the outward sum of
# 'give' and the inward sum of 'take' both equal to 62.5, so in
# edges (i,j) the node i tends to have above average 'give' and j
# tends to have above average 'take'
y<- san(x ~ edges + nodeocov('give') + nodeicov('take'), target.stats = c(100, 62.5, 62.5))
# check results
summary(y ~ edges + nodeocov('give') + nodeicov('take'))
# initialize x to a random undirected network with 50 nodes
x <- network(50, directed = FALSE)
# add a vertex attribute
x %v% 'popularity' <- runif(50, 0, 1)
# try to find a set of }100\mathrm{ edges making the total sum of
# popularity(i) and popularity(j) over all edges (i,j) equal to
# 125, so nodes with higher popularity are more likely to be
# connected to other nodes
y <- san(x ~ edges + nodecov('popularity'), target.stats = c(100, 125))
# check results
summary(y ~ edges + nodecov('popularity'))
# creates a network with denser "core" spreading out to sparser
# "periphery"
plot(y)
```

```
search.ergmConstraints
```

## Description

Searches through the ergm. constraints help page and prints out a list of constraints appropriate for the specified network's structural constraints, optionally restricting by additional keywords and search term matches.

## Usage

search.ergmConstraints(search, keywords, name, packages)

## Arguments

search
keywords optional character vector of keyword tags to use to restrict the results (i.e. 'curved', 'triad-related')
name optional character name of a specific constraint to return
packages optional character vector indicating the subset of packages in which to search

## Details

Uses grep internally to match the search terms against the constraint description, so search is currently matched as a single phrase. Keyword tags will only return a match if all of the specified tags are included in the constraint

## Value

prints out the name and short description of matching constraints, and invisibly returns them as a list. If name is specified, prints out the full definition for the named constraint.

## Author(s)

skyebend@uw.edu

## See Also

See also ergm. constraints for the complete documentation

## Examples

```
# find all of the constraint that mention degrees
search.ergmConstraints('degree')
# search on multiple keywords
search.ergmConstraints(keywords=c('directed','dyad-independent'))
# print out the content for a specific constraint
search.ergmConstraints(name='b1degrees')
# request the bipartite keyword in the ergm package
```

```
search.ergmConstraints(keywords='directed', packages='ergm')
```

search.ergmProposals Search the ERGM Proposals

## Description

Searches through the ergm. proposals help page and prints out a list of proposals appropriate for the specified network's structural constraints, optionally restricting by additional keywords and search term matches.

## Usage

search.ergmProposals(search, name, reference, constraints, packages)

## Arguments

| search | optional character search term to search for in the text of the term descriptions. <br> Only matching terms will be returned. Matching is case insensitive. |
| :--- | :--- |
| name | optional character name of a specific proposal to return |
| reference | optional character to limit proposals to only those with a matching reference |
| constraints | optional character vector to limit proposals to only those with matching hard or <br> soft constraints |
| packages | optional character vector indicating the subset of packages in which to search |

## Details

Uses grep internally to match the search terms against the proposal description, so search is currently matched as a single phrase. Keyword tags will only return a match if all of the specified tags are included in the proposal

## Value

prints out the name and short description of matching terms, and invisibly returns them as a list. If name is specified, prints out the full definition for the named term.

## See Also

See also ergm. proposals for the complete documentation

## Examples

```
# find all of the proposals that mention triangles
search.ergmProposals('MH algorithm')
# print out the content for a specific proposals
search.ergmProposals(name='randomtoggle')
# find all proposals with required or optional constraints
search.ergmProposals(constraints='.dyads')
# find all proposals with references
search.ergmProposals(reference='Bernoulli')
# request proposals that mention triangle in the ergm package
search.ergmProposals('MH algorithm', packages='ergm')
```

search.ergmReferences Search the ERGM References

## Description

Searches through the ergm. references help page and prints out a list of terms appropriate for the specified network's structural constraints, optionally restricting by additional keywords and search term matches.

## Usage

search.ergmReferences(search, keywords, name, packages)

## Arguments

$$
\begin{array}{ll}
\text { search } & \begin{array}{l}
\text { optional character search term to search for in the text of the term descriptions. } \\
\text { Only matching terms will be returned. Matching is case insensitive. }
\end{array} \\
\text { keywords } & \begin{array}{l}
\text { optional character vector of keyword tags to use to restrict the results (i.e. 'curved', } \\
\text { 'triad-related') }
\end{array} \\
\text { name } & \begin{array}{l}
\text { optional character name of a specific term to return }
\end{array} \\
\text { packages } & \text { optional character vector indicating the subset of packages in which to search }
\end{array}
$$

## Details

Uses grep internally to match the search terms against the term description, so search is currently matched as a single phrase. Keyword tags will only return a match if all of the specified tags are included in the term.

## Value

prints out the name and short description of matching terms, and invisibly returns them as a list. If name is specified, prints out the full definition for the named term.

## Author(s)

skyebend@uw.edu

## See Also

See also ergm. references for the complete documentation

## Examples

```
# find all of the references that mention dyad
search.ergmReferences('dyad')
# search on multiple keywords
search.ergmReferences(keywords=c('binary','discrete'))
# print out the content for a specific reference
search.ergmReferences(name='Bernoulli')
# request the bipartite keyword in the ergm package
search.ergmReferences(keywords='binary', packages='ergm')
```

search.ergmTerms Search the ERGM terms

## Description

Searches through the ergm. terms help page and prints out a list of terms appropriate for the specified network's structural constraints, optionally restricting by additional keywords and search term matches.

## Usage

search.ergmTerms(search, net, keywords, name, packages)

## Arguments

search optional character search term to search for in the text of the term descriptions. Only matching terms will be returned. Matching is case insensitive.
net a network object that the term would be applied to, used as template to determine directedness, bipartite, etc
keywords optional character vector of keyword tags to use to restrict the results (i.e. 'curved', 'triad-related')

| name | optional character name of a specific term to return |
| :--- | :--- |
| packages | optional character vector indicating the subset of packages in which to search |

## Details

Uses grep internally to match the search terms against the term description, so search is currently matched as a single phrase. Keyword tags will only return a match if all of the specified tags are included in the term.

## Value

prints out the name and short description of matching terms, and invisibly returns them as a list. If name is specified, prints out the full definition for the named term.

## Author(s)

skyebend@uw.edu

## See Also

See also ergm. terms for the complete documentation

## Examples

```
# find all of the terms that mention triangles
search.ergmTerms('triangle')
# two ways to search for bipartite terms:
# search using a bipartite net as a template
myNet<-network.initialize(5,bipartite=3)
search.ergmTerms(net=myNet)
# or request the bipartite keyword
search.ergmTerms(keywords='bipartite')
# search on multiple keywords
search.ergmTerms(keywords=c('bipartite','dyad-independent'))
# print out the content for a specific term
search.ergmTerms(name='b2factor')
# request the bipartite keyword in the ergm package
search.ergmTerms(keywords='bipartite', packages='ergm')
```

## Description

This term adds one network statistic for each node equal to the number of out-ties for that node. This measures the activity of the node. The term for the first node is omitted by default because of linear dependence that arises if this term is used together with edges, but its coefficient can be computed as the negative of the sum of the coefficients of all the other actors. That is, the average coefficient is zero, following the Holland-Leinhardt parametrization of the \$p_1\$ model (Holland and Leinhardt, 1981).

For undirected networks, see sociality .

## Usage

\# binary: sender(base=1, nodes=-1)
\# valued: sender(base=1, nodes=-1, form="sum")

## Arguments

| base | deprecated |
| :--- | :--- |
| nodes | specify which nodes' statistics should be included or excluded (see Specifying <br> Vertex attributes and Levels (?nodal_attributes) for details) |
| form | character how to aggregate tie values in a valued ERGM |

Note
The argument base is retained for backwards compatibility and may be removed in a future version. When both base and nodes are passed, nodes overrides base.

This term can only be used with directed networks.

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

This term adds one statistic to the model equal to the number of Simmelian triads, as defined by Krackhardt and Handcock (2007). This is a complete sub-graph of size three.

## Usage

\# binary: simmelian

Note
This term can only be used with directed networks.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
simmelianties-ergmTerm
```

Ties in simmelian triads

## Description

This term adds one statistic to the model equal to the number of ties in the network that are associated with Simmelian triads, as defined by Krackhardt and Handcock (2007). Each Simmelian has six ties in it but, because Simmelians can overlap in terms of nodes (and associated ties), the total number of ties in these Simmelians is less than six times the number of Simmelians. Hence this is a measure of the clustering of Simmelians (given the number of Simmelians).

## Usage

\# binary: simmelianties

## Note

This term can only be used with directed networks.

## See Also

ergmTerm for index of model terms currently visible to the package.

## simulate.ergm Draw from the distribution of an Exponential Family Random Graph

 Model
## Description

simulate is used to draw from exponential family random network models. See ergm for more information on these models.
The method for ergm objects inherits the model, the coefficients, the response attribute, the reference, the constraints, and most simulation parameters from the model fit, unless overridden by passing them explicitly. Unless overridden, the simulation is initialized with a random draw from the fitted model, saved by ergm().

## Usage

```
## S3 method for class 'formula_lhs_network'

    simplify = TRUE,
    sequential = TRUE,
    control = control.simulate.ergm(),
    verbose = FALSE,
    ...
)
```

## Arguments

object Either a formula or an ergm object. The formula should be of the form $y$ ~ <model terms>, where $y$ is a network object or a matrix that can be coerced to a network object. For the details on the possible <model terms>, see ergmTerm. To create a network object in, use the network() function, then add nodal attributes to it using the \%v\% operator if necessary.
nsim Number of networks to be randomly drawn from the given distribution on the set of all networks, returned by the Metropolis-Hastings algorithm.
seed Seed value (integer) for the random number generator. See set. seed.
... Further arguments passed to or used by methods.
basis a value (usually a network) to override the LHS of the formula.
coef Vector of parameter values for the model from which the sample is to be drawn. If object is of class ergm, the default value is the vector of estimated coefficients. Can be set to NULL to bypass, but only if return. args below is used.

| response | Either a character string, a formula, or NULL (the default), to specify the response attributes and whether the ERGM is binary or valued. Interpreted as follows: <br> NULL Model simple presence or absence, via a binary ERGM. <br> character string The name of the edge attribute whose value is to be modeled. Type of ERGM will be determined by whether the attribute is logical (TRUE/FALSE) for binary or numeric for valued. <br> a formula must be of the form NAME~EXPR\|TYPE (with | being literal). EXPR is evaluated in the formula's environment with the network's edge attributes accessible as variables. The optional NAME specifies the name of the edge attribute into which the results should be stored, with the default being a concise version of EXPR. Normally, the type of ERGM is determined by whether the result of evaluating EXPR is logical or numeric, but the optional TYPE can be used to override by specifying a scalar of the type involved (e.g., TRUE for binary and 1 for valued). |
| :---: | :---: |
| reference | A one-sided formula specifying the reference measure $(h(y))$ to be used. See help for ERGM reference measures implemented in the ergm package. |
| constraints | A one-sided formula specifying one or more constraints on the support of the distribution of the networks being simulated. See the documentation for a similar argument for ergm and see list of implemented constraints for more information. For simulate.formula, defaults to no constraints. For simulate.ergm, defaults to using the same constraints as those with which object was fitted. |
| observational | Inherit observational constraints rather than model constraints. |
| monitor | A one-sided formula specifying one or more terms whose value is to be monitored. These terms are appended to the model, along with a coefficient of 0 , so their statistics are returned. An ergm_model objectcan be passed as well. |
| statsonly | Logical: If TRUE, return only the network statistics, not the network(s) themselves. Deprecated in favor of output=. |
| esteq | Logical: If TRUE, compute the sample estimating equations of an ERGM: if the model is non-curved, all non-offset statistics are returned either way, but if the model is curved, the score estimating function values (3.1) by Hunter and Handcock (2006) are returned instead. |
| output | Normally character, one of "network" (default), "stats", "edgelist", or "ergm_state": determines the output format. Partial matching is performed. |
|  | Alternatively, a function with prototype function(ergm_state, chain, iter, ...) that is called for each returned network, and its return value, rather than the network itself, is stored. This can be used to, for example, store the simulated networks to disk without storing them in memory or compute network statistics not implemented using the ERGM API, without having to store the networks themselves. |
| simplify | Logical: If TRUE the output is "simplified": sampled networks are returned in a single list, statistics from multiple parallel chains are stacked, etc.. This makes it consistent with behavior prior to ergm 3.10. |
| sequential | Logical: If FALSE, each of the nsim simulated Markov chains begins at the initial network. If TRUE, the end of one simulation is used as the start of the next. Irrelevant when nsim=1. |

| control | A list of control parameters for algorithm tuning, typically constructed with <br> control.simulate.ergm() or control.simulate.formula(), which have dif- <br> ferent defaults. Their documentation gives the the list of recognized control pa- <br> rameters and their meaning. The more generic utility snctrl() (StatNet Con- <br> TRoL) also provides argument completion for the available control functions <br> and limited argument name checking. |
| :--- | :--- |
| verbose | A logical or an integer to control the amount of progress and diagnostic in- <br> formation to be printed. FALSE/0 produces minimal output, wit higher values <br> producing more detail. Note that very high values (5+) may significantly slow <br> down processing. |
| do.sim | Logical; a deprecated interface superseded by return.args, that saves the in- <br> puts to the next level of the function. |
| return.args | Character; if not NULL, the simulate method for that particular class will, in- <br> stead of proceeding for simulation, instead return its arguments as a list that can <br> be passed as a second argument to do.call() or a lower-level function such <br> as ergm_MCMC_sample(). This can be useful if, for example, one wants to run <br> several simulations with varying coefficients and does not want to reinitialize |
| the model and the proposal every time. Valid inputs at this time are "formula", |  |
| "ergm_model", and one of the "ergm_state" classes, for the three respective |  |

## Details

A sample of networks is randomly drawn from the specified model. The model is specified by the first argument of the function. If the first argument is a formula then this defines the model. If the first argument is the output of a call to ergm then the model used for that call is the one fit - and unless coef is specified, the sample is from the MLE of the parameters. If neither of those are given as the first argument then a Bernoulli network is generated with the probability of ties defined by prob or coef.
Note that the first network is sampled after burnin steps, and any subsequent networks are sampled each interval steps after the first.
More information can be found by looking at the documentation of ergm.

## Value

If output=="stats" an mcmc object containing the simulated network statistics. If control\$parallel>0, an mcmc.list object. If simplify=TRUE (the default), these would then be "stacked" and converted to a standard matrix. A logical vector indicating whether or not the term had come from the monitor= formula is stored in attr()-style attribute "monitored".
Otherwise, a representation of the simulated network is returned, in the form specified by output. In addition to a network representation or a list thereof, they have the following attr-style attributes:
formula The formula used to generate the sample.
stats An mcmc or memc. list object as above.
control Control parameters used to generate the sample.
constraints Constraints used to generate the sample.
reference The reference measure for the sample.
monitor The monitoring formula.
response The edge attribute used as a response.
The following are the permitted network formats:
"network" If nsim==1, an object of class network. If nsim>1, it returns an object of class network. list (a list of networks) with the above-listed additional attributes.
"edgelist" An edgelist representation of the network, or a list thereof, depending on nsim.
"ergm_state" A semi-internal representation of a network consisting of a network object emptied of edges, with an attached edgelist matrix, or a list thereof, depending on nsim.

If simplify==FALSE, the networks are returned as a nested list, with outer list being the parallel chain (including 1 for no parallelism) and inner list being the samples within that chains (including 1 , if one network per chain). If TRUE, they are concatenated, and if a total of one network had been simulated, the network itself will be returned.

## Functions

- simulate.ergm_state_full: a low-level function to simulate from an ergm_state object.

## Note

simulate.ergm_model() is a lower-level interface, providing a simulate() method for ergm_model class. The basis argument is required; monitor, if passed, must be an ergm_model as well; and constraints can be an ergm_proposal object instead.

## See Also

ergm, network, ergm_MCMC_sample() for a demonstration of return.args=.

## Examples

```
#
# Let's draw from a Bernoulli model with 16 nodes
# and density 0.5 (i.e., coef = c(0,0))
#
g.sim <- simulate(network(16) ~ edges + mutual, coef=c(0, 0))
#
# What are the statistics like?
#
summary(g.sim ~ edges + mutual)
#
# Now simulate a network with higher mutuality
#
g.sim <- simulate(network(16) ~ edges + mutual, coef=c(0,2))
#
# How do the statistics look?
#
summary(g.sim ~ edges + mutual)
#
```

```
# Let's draw from a Bernoulli model with 16 nodes
# and tie probability 0.1
#
g.use <- network(16,density=0.1,directed=FALSE)
#
# Starting from this network let's draw 3 realizations
# of a edges and 2-star network
#
g.sim <- simulate(~edges+kstar(2), nsim=3, coef=c(-1.8,0.03),
            basis=g.use, control=control.simulate(
                MCMC.burnin=1000,
                MCMC. interval=100))
g.sim
summary(g.sim)
#
# attach the Florentine Marriage data
#
data(florentine)
#
# fit an edges and 2-star model using the ergm function
#

summary(gest)
#
# Draw from the fitted model (statistics only), and observe the number
# of triangles as well.
#
g.sim <- simulate(gest, nsim=10,
    monitor=~triangles, output="stats",
    control=control.simulate.ergm(MCMC.burnin=1000, MCMC.interval=100))
g.sim
# Custom output: store the edgecount (computed in R), iteration index, and chain index.
output.f <- function(x, iter, chain, ...){
    list(nedges = network.edgecount(as.network(x)),
        chain = chain, iter = iter)
}
g.sim <- simulate(gest, nsim=3,
                        output=output.f, simplify=FALSE,
        control=control.simulate.ergm(MCMC.burnin=1000, MCMC.interval=100))
unclass(g.sim)
```

| simulate.formula | A simulate Method for formula objects that dispatches based on the |
| :--- | :--- |
| Left-Hand Side |  |

## Description

This method evaluates the left-hand side (LHS) of the given formula and dispatches it to an appropriate method based on the result by setting an nonce class name on the formula.

## Usage

```
## S3 method for class 'formula'
simulate(object, nsim = 1, seed = NULL, ..., basis, newdata, data)
## S3 method for class 'formula_lhs'
simulate(object, nsim = 1, seed = NULL, ...)
```

## Arguments

object a one- or two-sided formula.
nsim, seed number of realisations to simulate and the random seed to use; see simulate().
.. additional arguments to methods.
basis if given, overrides the LHS of the formula for the purposes of dispatching.
newdata, data if passed, the object's LHS is evaluated in this environment; at most one of the two may be passed.
The dispatching works as follows:

1. If basis is not passed, and the formula has an LHS the expression on the LHS of the formula in the object is evaluated in the environment newdata or data (if given), in any case enclosed by the environment of object. Otherwise, basis is used.
2. The result is set as an attribute ". Basis" on object. If there is no basis or LHS, it is not set.
3. The class vector of object has c("formula_lhs_CLASS", "formula_lhs") prepended to it, where CLASS is the class of the LHS value or basis. If LHS or basis has multiple classes, they are all prepended; if there is no LHS or basis, c("formula_lhs_", "formula_lhs") is.
4. simulate() generic is evaluated on the new object, with all arguments passed on, excluding basis; if newdata or data are missing, they too are not passed on. The evaluation takes place in the parent's environment.

A "method" to receive a formula whose LHS evaluates to CLASS can therefore be implemented by a function simulate.formula_lhs_\var\{CLASS\}(). This function can expect a formula object, with additional attribute .Basis giving the evaluated LHS (so that it does not need to be evaluated again).

## Functions

- simulate.formula_lhs: A function to catch the situation when there is no method implemented for the class to which the LHS evaluates.

## See Also

simulate. $\operatorname{ergm}()$ family of functions, which uses this interface.
smalldiff-ergmTerm $\quad$ Number of ties between actors with similar attribute values

## Description

This term adds one statistic, having as its value the number of edges in the network for which the incident actors' attribute values differ less than cutoff ; that is, number of edges between $i$ to $j$ such that abs (attr[i]-attr[j])<cutoff.

## Usage

\# binary: smalldiff(attr, cutoff)

## Arguments

| attr | quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) |
| :--- | :--- |
| for details.) |  |

## See Also

ergmTerm for index of model terms currently visible to the package.

```
smallerthan-ergmTerm Number of dyads with values strictly smaller than a threshold
```

## Description

Adds the number of statistics equal to the length of threshold equaling to the number of dyads whose values are exceeded by the corresponding element of threshold.

## Usage

\# valued: smallerthan(threshold=0)

## Arguments

threshold vector of numerical values

## See Also

ergmTerm for index of model terms currently visible to the package.

## snctrl Statnet Control

## Description

A utility to facilitate argument completion of control lists, reexported from statnet. common.

## Currently recognised control parameters

This list is updated as packages are loaded and unloaded.

## Package ergm:

statnet.common::snctrl()

```
sociality-ergmTerm Undirected degree
```

## Description

This term adds one network statistic for each node equal to the number of ties of that node. For directed networks, see sender and receiver.

## Usage

\# binary: sociality(attr=NULL, base=1, levels=NULL, nodes=-1)
\# valued: sociality(attr=NULL, base=1, levels=NULL, nodes=-1, form="sum")

## Arguments

$$
\begin{array}{ll}
\text { attr, levels } & \begin{array}{l}
\text { this optional argument is deprecated and will be replaced with a more elegant } \\
\text { implementation in a future release. In the meantime, it specifies a categorical } \\
\text { vertex attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) } \\
\text { for details). If provided, this term only counts ties between nodes with the } \\
\text { same value of the attribute (an actor-specific version of the nodematch term), re- } \\
\text { stricted to be one of the values specified by (also deprecated) levels if levels } \\
\text { is not NULL. }
\end{array} \\
\text { base } & \begin{array}{l}
\text { deprecated } \\
\text { nodes } \\
\text { By default, nodes=-1 means that the statistic for the first node will be omitted, } \\
\text { but this argument may be changed to control which statistics are included just } \\
\text { as for the nodes argument of sender and receiver terms. } \\
\text { character how to aggregate tie values in a valued ERGM }
\end{array} \\
\text { form } & \begin{array}{l}
\text { chat }
\end{array} \\
&
\end{array}
$$

## Note

The argument base is retained for backwards compatibility and may be removed in a future version. When both base and levels are passed, levels overrides base.
The argument base is retained for backwards compatibility and may be removed in a future version. When both base and nodes are passed, nodes overrides base.
This term can only be used with undirected networks.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
    sparse-ergmHint Sparse network
```

## Description

The network is sparse. This typically results in a Tie-Non-Tie (TNT) proposal regime.

## Usage

\# sparse

## See Also

ergmHint for index of constraints and hints currently visible to the package.

```
spectrum0.mvar Multivariate version of coda's spectrum0.ar().
```

## Description

Its return value, divided by nrow $(\operatorname{cbind}(x))$, is the estimated variance-covariance matrix of the sampling distribution of the mean of x if x is a multivatriate time series with $\operatorname{AR}(p)$ structure, with $p$ determined by AIC.

## Usage

```
spectrum0.mvar(
    x,
    order.max = NULL,
    aic = is.null(order.max),
    tol = .Machine$double.eps^0.5,
    ...
    )
```

## Arguments

X
order.max
aic
tol drop components until the reciprocal condition number of the transformed variancecovariance matrix is greater than this.
.. additional arguments to $\operatorname{ar}()$.

## Value

A square matrix with dimension equalling to the number of columns of $x$, with an additional attribute "infl" giving the factor by which the effective sample size is reduced due to autocorrelation, according to the Vats, Flegal, and Jones (2015) estimate for ESS.

## Note

$\operatorname{ar}()$ fails if crossprod $(x)$ is singular, which is remedied by mapping the variables onto the principal components of $x$, dropping redundant dimentions.

```
StdNormal-ergmReference
```

Standard Normal reference

## Description

Specifies each dyad's baseline distribution to be the normal distribution with mean 0 and variance 1.

## Usage

\# StdNormal

## See Also

ergmReference for index of reference distributions currently visible to the package.

```
strat-ergmHint Stratified dyads
```

## Description

The dyads in the network are stratified according to an attribute combination. This typically results in stratifying proposals by mixing type on a vertex attribute.

## Usage

\# strat(attr=NULL, pmat=NULL, empirical=FALSE)

## Details

The user may pass a vertex attribute attr as an argument (the default for attr gives every vertex the same attribute value), and may also pass a matrix of weights pmat (the default for pmat gives equal weight to each mixing type). See Specifying Vertex Attributes and Levels for details on specifying vertex attributes. The matrix pmat, if specified, must have the same dimensions as a mixing matrix for the network and attribute under consideration, and the correspondence between rows and columns of pmat and values of attr is the same as for a mixing matrix.
The interpretation is that pmat $[i, j] / s u m(p m a t)$ is the probability of proposing a toggle for mixing type $(i, j)$. (For undirected, unipartite networks, pmat is first symmetrized, and then entries below the diagonal are set to zero. Only entries on or above the diagonal of the symmetrized pmat are considered when making proposals. This accounts for the convention that mixing is undirected in an undirected, unipartite network: a tail of type $i$ and a head of type $j$ has the same mixing type as a tail of type $j$ and a head of type i.)
As an alternative way of specifying pmat, the user may pass empirical=TRUE to use the mixing matrix of the network beginning the MCMC chain as pmat. In order for this to work, that network should have a reasonable (in particular, nonempty) edge set.
While some mixing types may be assigned zero proposal probability (either with a direct specification of pmat or with empirical=TRUE ), this will not be recognized as a constraint by all components of ergm, and should be used with caution.

## See Also

ergmHint for index of constraints and hints currently visible to the package.
sum-ergmTerm Sum of dyad values (optionally taken to a power)

## Description

This term adds one statistic equal to the sum of dyad values taken to the power pow.

## Usage

\# valued: sum(pow=1)

## Arguments

pow power of dyad values. Defaults to 1.

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

This operator sums up the RHS statistics of the input formulas elementwise.

## Usage

\# binary: Sum(formulas, label)
\# valued: Sum(formulas, label)

## Arguments

formulas a list (constructed using list() or c()) of ergm()-style formulas whose RHS gives the statistics to be evaluated, or a single formula.
If a formula in the list has an LHS, it is interpreted as follows:

- a numeric scalar: Network statistics of this formula will be multiplied by this.
- a numeric vector: Corresponding network statistics of this formula will be multiplied by this.
- a numeric matrix: Vector of network statistics will be pre-multiplied by this.
- a character string: One of several predefined linear combinations. Currently supported presets are as follows:
- "sum" Network statistics of this formula will be summed up; equivalent to matrix $(1,1, p)$, where $p$ is the length of the network statistic vector.
- "mean" Network statistics of this formula will be averaged; equivalent to matrix $(1 / p, 1, p)$, where $p$ is the length of the network statistic vector.
label used to specify the names of the elements of the resulting term sum vector. If label is a character vector of length 1 , it will be recycled with indices appended. If a function is specified, formulas parameter names are extracted and their list of character vectors is passed label.

## Details

Note that each formula must either produce the same number of statistics or be mapped through a matrix to produce the same number of statistics.

A single formula is also permitted. This can be useful if one wishes to, say, scale or sum up the statistics returned by a formula.

Offsets are ignored unless there is only one formula and the transformation only scales the statistics (i.e., the effective transformation matrix is diagonal).

Curved models are supported, subject to some limitations. In particular, the first model's etamap will be used, overwriting the others. If label is not of length 1, it should have an attr -style attribute "curved" specifying the names for the curved parameters.

```
summary.ergm Summarizing ERGM Model Fits
```

## Description

```
base::summary() method for ergm() fits.
```

## Usage

```
## S3 method for class 'ergm'
summary(
    object,
    ...,
    correlation = FALSE,
    covariance = FALSE,
    total.variation = TRUE
)
## S3 method for class 'summary.ergm'
print(
    x,
    digits = max(3, getOption("digits") - 3),
    correlation = x$correlation,
    covariance = x$covariance,
    signif.stars = getOption("show.signif.stars"),
    eps.Pvalue = 1e-04,
    print.formula = FALSE,
    print.fitinfo = TRUE,
    print.coefmat = TRUE,
    print.message = TRUE,
    print.deviances = TRUE,
    print.drop = TRUE,
    print.offset = TRUE,
    print.call = TRUE,
)
```

## Arguments

object an object of class "ergm", usually, a result of a call to ergm().
... For summary.ergm() additional arguments are passed to logLik.ergm(). For print. summary.ergm(), to stats: :printCoefmat().
correlation logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
covariance logical; if TRUE, the covariance matrix of the estimated parameters is returned and printed.
total.variation
logical; if TRUE, the standard errors reported in the Std. Error column are based on the sum of the likelihood variation and the MCMC variation. If FALSE only the likelihood variation is used. The $p$-values are based on this source of variation.
$x \quad$ object of class summary .ergm returned by summary. ergm().
digits significant digits for coefficients
signif.stars whether to print dots and stars to signify statistical significance. See print. summary. 1 m() .
eps.Pvalue $\quad p$-values below this level will be printed as "<eps.Pvalue".
print.formula, print.fitinfo, print.coefmat, print.message, print.deviances, print.drop, print.offset, which components of the fit summary to print.

## Details

summary. ergm() tries to be smart about formatting the coefficients, standard errors, etc.
The default printout of the summary object contains the call, number of iterations used, null and residual deviances, and the values of AIC and BIC (and their MCMC standard errors, if applicable). The coefficient table contains the following columns:

- Estimate, Std. Error - parameter estimates and their standard errors
- MCMC \% - if total.variation=TRUE (default) the percentage of standard error attributable to MCMC estimation process rounded to an integer. See also vcov.ergm() and its sources argument.
- z value, $\operatorname{Pr}(>|z|)$ - z-test and $p$-values

## Value

The returned object is a list of class "ergm.summary" with the following elements:

```
formula ERGM model formula
call R call used to fit the model
correlation, covariance
    whether to print correlation/covariance matrices of the estimated parameters
pseudolikelihood
    was the model estimated with MPLE
    independence is the model dyad-independent
```

```
control the control.ergm() object used
samplesize MCMC sample size
message optional message on the validity of the standard error estimates
null.lik.0 It is TRUE of the null model likelihood has not been calculated. See logLikNull()
devtext, devtable
    Deviance type and table
aic, bic values of AIC and BIC
coefficients matrices with model parameters and associated statistics
asycov asymptotic covariance matrix
asyse asymptotic standard error matrix
offset, drop, estimate, iterations, mle.lik, null.lik
    see documentation of the object returned by ergm()
```

## See Also

summary(x)
```

summary.formula Calculation of network or graph statistics or other attributes specified on a formula

## Description

Most generally, this function computes those summaries of the object on the LHS of the formula that are specified by its RHS. In particular, if given a network as its LHS and ergmTerm on its RHS, it computes the sufficient statistics associated with those terms.

## Usage

\#\# S3 method for class 'formula'
summary (object, ...)

## Arguments

object A formula having as its LHS a network object or a matrix that can be coerced to a network object, a network. list, or other types to be summarized using a formula. (See 'methods('summary_formula') for the possible LHS types.
... further arguments passed to or used by methods.

## Details

In practice, summary. formula() is a thin wrapper around the summary_formula() generic, which dispatches methods based on the class of the LHS of the formula.

## Value

A vector of statistics specified in RHS of the formula.

## See Also

```
ergm(), network(), ergmTerm
```

## Examples

\#
\# Lets look at the Florentine marriage data
\#
data(florentine)
\#
\# test the summary_formula function
\#
summary (flomarriage ~ edges + kstar(2))
m <- as.matrix(flomarriage)
summary ( $m$ ~ edges) \# twice as large as it should be
summary ( $m$ ~ edges, directed=FALSE) \# Now it's correct

Symmetrize-ergmTerm Evaluation on symmetrized (undirected) network

## Description

Evaluates the terms in formula on an undirected network constructed by symmetrizing the LHS network using one of four rules:

1. "weak" A tie $(i, j)$ is present in the constructed network if the LHS network has either tie $(i, j)$ or $(j, i)$ (or both).
2. "strong" A tie $(i, j)$ is present in the constructed network if the LHS network has both tie $(i, j)$ and tie $(j, i)$.
3. "upper" A tie $(i, j)$ is present in the constructed network if the LHS network has tie $(\min (i, j), \max (i, j))$ : the upper triangle of the LHS network.
4. "lower" A tie $(i, j)$ is present in the constructed network if the LHS network has tie $(\max (i, j), \min (i, j))$ : the lower triangle of the LHS network.

## Usage

\# binary: Symmetrize(formula, rule="weak")

## Arguments

```
formula a one-sided ergm()-style formula with the terms to be evaluated
    rule one of "weak", "strong", "upper", "lower"
```

## See Also

ergmTerm for index of model terms currently visible to the package.

```
transitive-ergmTerm Transitive triads
```

## Description

This term adds one statistic to the model, equal to the number of triads in the network that are transitive. The transitive triads are those of type 120D, 030T, 120U, or 300 in the categorization of Davis and Leinhardt (1972). For details on the 16 possible triad types, see ?triad.classify in the sna package. Note the distinction from the ttriple term. This term can only be used with directed networks.

## Usage

\# binary: transitive

## See Also

ergmTerm for index of model terms currently visible to the package.

```
transitiveties-ergmTerm
```

Transitive ties

## Description

This term adds one statistic, equal to the number of ties $i \rightarrow j$ such that there exists a two-path from $i$ to $j$. (Related to the ttriple term.)

## Usage

\# binary: transitiveties(attr=NULL, levels=NULL)

## Arguments

attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes)
for details.) If set, all three nodes involved ( $i, j$, and the node on the two-path)
must match on this attribute in order for $i \rightarrow j$ to be counted.
levels TODO (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)

## See Also

ergmTerm for index of model terms currently visible to the package.

```
transitiveweights-ergmTerm
```

## Transitive weights

## Description

This statistic implements the transitive weights statistic defined by Krivitsky (2012), Equation 13. For each of these options, the first (and the default) is more stable but also more conservative, while the second is more sensitive but more likely to induce a multimodal distribution of networks.

## Usage

\# valued: transitiveweights(twopath="min", combine="max", affect="min")

## Arguments

twopath the minimum of the constituent dyads ( "min") or their geometric mean ( "geomean")
combine the maximum of the 2-path strengths ("max") or their sum ("sum" )
affect the minimum of the focus dyad and the combined strength of the two paths ( "min") or their geometric mean ("geomean")

## See Also

ergmTerm for index of model terms currently visible to the package.

```
triadcensus-ergmTerm Triad census
```

## Description

For a directed network, this term adds one network statistic for each of an arbitrary subset of the 16 possible types of triads categorized by Davis and Leinhardt (1972) as 003, 012, 102, 021D, 021U, 021C, 111D, 111U, 0 and 300 . Note that at least one category should be dropped; otherwise a linear dependency will exist among the 16 statistics, since they must sum to the total number of three-node sets. By default, the category 003 , which is the category of completely empty three-node sets, is dropped. This is considered category zero, and the others are numbered 1 through 15 in the order given above. Each statistic is the count of the corresponding triad type in the network. For details on the 16 types, see ?triad.classify in the sna package, on which this code is based. For an undirected network, the triad census is over the four types defined by the number of ties (i.e., $0,1,2$, and 3 ).

## Usage

\# binary: triadcensus(levels)

## Arguments

levels For directed networks, specify a set of terms to add other than the default value of $1: 15$. attributes and Levels (?nodal_attributes) for details.)

## See Also

ergmTerm for index of model terms currently visible to the package.

```
triangle-ergmTerm Triangles
```

## Description

By default, this term adds one statistic to the model equal to the number of triangles in the network. For an undirected network, a triangle is defined to be any set $\{(i, j),(j, k),(k, i)\}$ of three edges. For a directed network, a triangle is defined as any set of three edges $(i \rightarrow j)$ and $(j \rightarrow k)$ and either $(k \rightarrow i)$ or $(k \leftarrow i)$. The former case is called a "transitive triple" and the latter is called a "cyclic triple", so in the case of a directed network, triangle equals ttriple plus ctriple - thus at most two of these three terms can be in a model.

## Usage

\# binary: triangle(attr=NULL, diff=FALSE, levels=NULL)
\# binary: triangles(attr=NULL, diff=FALSE, levels=NULL)

## Arguments

attr, diff quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.) If attr is specified and diff is FALSE, then the count is restricted to those triples of nodes with equal values of the vertex attribute specified by attr. If attr is specified and diff is TRUE, then one statistic is added for each value of attr, equal to the number of triangles where all three nodes have that value of the attribute.
levels add one statistic for each value specified if diff is TRUE. (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)

## See Also

ergmTerm for index of model terms currently visible to the package.

## Description

By default, this term adds one statistic to the model equal to 100 times the ratio of the number of triangles in the network to the sum of the number of triangles and the number of 2 -stars not in triangles (the latter is considered a potential but incomplete triangle). In case the denominator equals zero, the statistic is defined to be zero. For the definition of triangle, see triangle. This is often called the mean correlation coefficient. This term can only be used with undirected networks; for directed networks, it is difficult to define the numerator and denominator in a consistent and meaningful way.

## Usage

\# binary: tripercent(attr=NULL, diff=FALSE, levels=NULL)

## Arguments

$\begin{array}{ll}\text { attr, diff } & \begin{array}{l}\text { quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) } \\ \text { for details.) If attr is specified and diff is FALSE , then the counts are restricted } \\ \text { to those triples of nodes with equal values of the vertex attribute specified by } \\ \text { attr. ## See Also

ergmTerm for index of model terms currently visible to the package.

```
ttriple-ergmTerm Transitive triples
```

## Description

By default, this term adds one statistic to the model, equal to the number of transitive triples in the network, defined as a set of edges $\{(i \rightarrow j), j \rightarrow k),(i \rightarrow k)\}$. Note that triangle equals ttriple+ctriple for a directed network, so at most two of the three terms can be in a model.

```
Usage
    \# binary: ttriple(attr=NULL, diff=FALSE, levels=NULL)
    \# binary: ttriad
```

## Arguments

attr, diff quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.) If attr is specified and diff is FALSE, then the count is over the number of transitive triples where all three nodes have the same value of the attribute. If attr is specified and diff is TRUE, then one statistic is added for each value of attr, equal to the number of triangles where all three nodes have that value of the attribute.
levels add one statistic for each value specified if diff is TRUE. (See Specifying Vertex attributes and Levels (?nodal_attributes) for details.)
attr quantitative attribute (see Specifying Vertex attributes and Levels (?nodal_attributes) for details.)

## Note

This term can only be used with directed networks.

## See Also

ergmTerm for index of model terms currently visible to the package.

```
twopath-ergmTerm 2-Paths
```

## Description

This term adds one statistic to the model, equal to the number of 2-paths in the network. For a directed network this is defined as a pair of edges $(i \rightarrow j),(j \rightarrow k)$, where $i$ and $j$ must be distinct. That is, it is a directed path of length 2 from $i$ to $k$ via $j$. For directed networks a 2-path is also a mixed 2-star but the interpretation is usually different; see m2star. For undirected networks a twopath is defined as a pair of edges $\{i, j\},\{j, k\}$. That is, it is an undirected path of length 2 from $i$ to $k$ via $j$, also known as a 2 -star.

## Usage

\# binary: twopath

## See Also

ergmTerm for index of model terms currently visible to the package.

```
Unif-ergmReference Continuous Uniform reference
```

## Description

Specifies each dyad's baseline distribution to be continuous uniform between a and $\mathbf{b}: h(y)=1$, with the support being [a, b].

## Usage

\# Unif(a,b)

## Arguments

$\mathrm{a}, \mathrm{b} \quad$ minimum and maximum to the baseline discrete uniform distribution, both inclusive. Both values must be finite.

## See Also

ergmReference for index of reference distributions currently visible to the package.

```
update.network Update the edges in a network based on a matrix
```

## Description

Replaces the edges in a network object with the edges corresponding to the sociomatrix or edge list specified by new.

## Usage

```
## S3 method for class 'network'
update(object, ...)
    update_network(object, new, ...)
    ## S3 method for class 'matrix_edgelist'
    update_network(object, new, attrname = if (ncol(new) > 2) names(new)[3], ...)
    ## S3 method for class 'data.frame'
    update_network(object, new, attrname = if (ncol(new) > 2) names(new)[3], ...)
    ## S3 method for class 'matrix'
    update_network(object, new, matrix.type = NULL, attrname = NULL, ...)
    ## S3 method for class 'ergm_state'
    update_network(object, new, ...)
```

## Arguments

object a network object.
... Additional arguments; currently unused.
new Either an adjacency matrix (a matrix of values indicating the presence and/or the value of a tie from $i$ to $j$ ) or an edge list (a two-column matrix listing origin and destination node numbers for each edge, with an optional third column for the value of the edge).
attrname For a network with edge weights gives the name of the edge attribute whose names to set.
matrix.type One of "adjacency" or "edgelist" telling which type of matrix new is. Default is to use the which.matrix.type function.

## Value

A new network object with the edges specified by new and network and vertex attributes copied from the input network object. Input network is not modified.

## Functions

- update_network: dispatcher for network update based on the type of updating information.
- update_network.matrix_edgelist: a method for updating a network based on a matrixform edgelist
- update_network.data.frame: a method for updating a network based on an edgelist
- update_network.matrix: a method for updating a network based on a matrix
- update_network.ergm_state: a method for updating a network based on an ergm_state object.

\#
\# test the network. update function
\#
\# Create a Bernoulli network
rand.net <- network(network.size(flomarriage))
\# store the sociomatrix
rand.mat <- rand.net[,]
\# Update the network
update(flomarriage, rand.mat, matrix.type="adjacency")
\# Try this with an edgelist
rand.mat <- as.matrix.network.edgelist(flomarriage)[1:5,]
update(flomarriage, rand.mat, matrix.type="edgelist")
wtd.median Weighted Median

## Description

Compute weighted median.

## Usage

wtd.median(x, na.rm = FALSE, weight = FALSE)

## Arguments

| x | Vector of data, same length as weight |
| :--- | :--- |
| na.rm | Logical: Should NAs be stripped before computation proceeds? |
| weight | Vector of weights |

## Details

Uses a simple algorithm based on sorting.

## Value

Returns an empirical . 5 quantile from a weighted sample.
