Package 'ggmulti'

July 23, 2021

Type Package

Title High Dimensional Data Visualization

Version 1.0.4

Description It provides materials (i.e. 'serial axes' objects, Andrew's plot, various glyphs for scatter plot) to visualize high dimensional data.

License GPL-2

Depends R (>= 3.4.0), methods, ggplot2

Imports stats, utils, grid, dplyr, tidyr

Suggests png, tools, stringr, markdown, magrittr, gridExtra, tibble, testthat, grDevices, knitr, rmarkdown, tidyverse, gtable, covr, maps, nycflights13, ggplot2movies

RoxygenNote 7.1.1

LazyData true

Encoding UTF-8

VignetteBuilder knitr

Language en-US

NeedsCompilation no

R topics documented:

add_serialaxes_layers   *Layers for serial axes coordinate*

Description

Project the regular geom layers onto the serial axes coordinate.

Usage

```
add_serialaxes_layers(layer, plot, object, axes)
```

Arguments

layer	a layer object
plot	a ggplot object
object	some parameters used to modify this serial axes ggplot object (i.e. axes.sequence, ...)
axes	canvas sequence axes

Details

The class is determined by layers you add. For example, you want to add a boxplot layer on serial axes coordinate. By the ggplot syntax, it should be ggplot(data,mapping) + geom_boxplot() + coord_serialaxes() To make it work, object add_serialaxes_layers.GeomBoxplot must be created. In this function, some computations will be applied.

---

coord_radial *Radial axes*

Description

A radial (spider) coordinate. A wrapper of the function coord_polar() by forcing it linear.

Usage

```
coord_radial(theta = "x", start = 0, direction = 1, clip = "on")
```

Arguments

theta	variable to map angle to (x or y)
start	Offset of starting point from 12 o'clock in radians. Offset is applied clockwise or anticlockwise depending on value of direction.
direction	1, clockwise; -1, anticlockwise
clip	Should drawing be clipped to the extent of the plot panel? A setting of "on" (the default) means yes, and a setting of "off" means no. For details, please see coord_cartesian().

Details

The serial histogram and serial density cannot be applied on a radial coordinate yet.

Examples

```
if(require("dplyr")) {
ggplot(NBAstats2021, mapping = aes(colour = Playoff)) +
  geom_serialaxes(
    axes.sequence = c("PTS", "OPTS", "3PM", "O3PM", "PTS"),
      scaling = "variable"
    ) +
  coord_radial() +
  scale_x_continuous(
    breaks = 1:5,
    labels = c("Points",
               "Oppo Points",
               "3P Made",
               "Oppo 3P Made",
               "Points Per Game")) +
  scale_y_continuous(labels = NULL) +
  facet_wrap(~CONF)
  }
```

---

coord_serialaxes   *Serial axes coordinates*

Description

It is mainly used to visualize the high dimensional data set either on the parallel coordinate or the radial coordinate.

Usage

```
coord_serialaxes(
  axes.layout = c("parallel", "radial"),
  scaling = c("data", "variable", "observation", "none"),
  axes.sequence = character(0L),
  positive = TRUE,
  ...
)
```

Arguments

axes.layout	Serial axes layout, either "parallel" or "radial".
scaling	One of `data`, `variable`, `observation` or `none` (not suggested the layout is the same with `data`) to specify how the data is scaled.
axes.sequence	A vector with variable names that defines the axes sequence.
positive	If y is set as the density estimate, where the smoothed curved is faced to, right (`positive`) or left (`negative`) as vertical layout; up (`positive`) or down (`negative`) as horizontal layout?
...	other arguments used to modify layers

Details

Serial axes coordinate system (parallel or radial) is different from the Cartesian coordinate system or its transformed system (say `polar` in `ggplot2`) since it does not have a formal transformation (i.e. in polar coordinate system, "x = rcos(theta)", "y = rsin(theta)"). In serial axes coordinate system, mapping aesthetics does not really require "x" or "y". Any "non-aesthetics" components passed in the `mapping` system will be treated as an individual axis.

To project a common geom layer on such serialaxes, users can customize function `add_serialaxes_layers`.

Value

a ggproto object

Potential Risk

In package ggmulti, the function ggplot_build.gg is provided. At the ggplot construction time, the system will call ggplot_build.gg first. If the plot input is not a CoordSerialaxes coordinate system, the next method ggplot_build.ggplot will be called to build a "gg" plot; else some geometric transformations will be applied first, then the next method ggplot_build.ggplot will be executed. So, the potential risk is, if some other packages e.g. foo, also provide a function ggplot_build.gg that is used for their specifications but the namespace is beyond the ggmulti (ggmulti:::ggplot_build.gg is covered), error may occur. If so, please consider using the geom_serialaxes.

Examples

```
if(require("dplyr")) {
# Data
nba <- NBAstats2021 %>%
  mutate(
    dPTS = PTS - OPTS,
    dREB = REB - OREB,
    dAST = AST - OAST,
    dTO = TO - OTO
  )
# set sequence by `axes.sequence`
p <- ggplot(nba,
            mapping = aes(
              dPTS = dPTS,
              dREB = dREB,
              dAST = dAST,
              dTO = dTO,
              colour = Win
            )) +
       geom_path(alpha = 0.2) +
       coord_serialaxes(axes.layout = "radial") +
       scale_color_gradient(low="blue", high="red")
p
# quantile layer
p + geom_quantiles(quantiles = c(0.5),
                   colour = "green", size = 1.2)

# facet
p +
  facet_grid(Playoff ~ CONF)
}
```

---

dot_product   *Transformation Coefficients*

Description

The dimension of the original data set is n*p. It can be projected onto a n*k space. The functions below are to provide such transformations, e.g. the `Andrews` coefficient (a Fourier transformation) and the `Legendre` polynomials.

Usage

```
andrews(p = 4, k = 50 * (p - 1), ...)

legendre(p = 4, k = 50 * (p - 1), ...)
```

Arguments

p	The number of dimensions
k	The sequence length
...	Other arguments passed on to methods. Mainly used for customized transformation function

Value

A list contains two named components

1. vector: A length k vector (define the domain)

2. matrix: A p*k transformed coefficient matrix

References

Andrews, David F. "Plots of high-dimensional data." *Biometrics* (1972): 125-136.

Abramowitz, Milton, and Irene A. Stegun, eds. "Chapter 8" *Handbook of mathematical functions with formulas, graphs, and mathematical tables*. Vol. 55. US Government printing office, 1948.

Examples

```
x <- andrews(p = 4)
dat <- iris[, -5]
proj <- t(as.matrix(dat) %*% x$matrix)
matplot(x$vector, proj,
        type = "l", lty = 1,
        col = "black",
        xlab = "x",
        ylab = "Andrews coefficients",
        main = "Iris")
```

Geom-ggproto   *Base Geom ggproto classes for ggplot2*

Description

All geom_ functions (like geom_point) return a layer that contains a Geom object (like GeomPoint). The Geom object is responsible for rendering the data in the plot. Each of the Geom objects is a ggproto object, descended from the top-level Geom, and each implements various methods and fields. Compared to Stat and Position, Geom is a little different because the execution of the setup and compute functions is split up. setup_data runs before position adjustments, and draw_layer is not run until render time, much later. This means there is no setup_params because it's hard to communicate the changes.

Usage

```
GeomDensity_

GeomBar_

GeomImageGlyph

GeomPolygonGlyph

GeomQuantiles

GeomSerialaxesDensity

GeomSerialAxesGlyph

GeomSerialaxesHist

GeomSerialaxesQuantile

GeomSerialaxes
```

Format

An object of class GeomDensity_ (inherits from GeomRibbon, Geom, ggproto, gg) of length 6.

An object of class GeomBar_ (inherits from GeomBar, GeomRect, Geom, ggproto, gg) of length 4.

An object of class GeomImageGlyph (inherits from Geom, ggproto, gg) of length 7.

An object of class GeomPolygonGlyph (inherits from Geom, ggproto, gg) of length 7.

An object of class GeomQuantiles (inherits from GeomQuantile, GeomPath, Geom, ggproto, gg) of length 1.

An object of class GeomSerialaxesDensity (inherits from GeomDensity_, GeomRibbon, Geom, ggproto, gg) of length 2.

An object of class `GeomSerialAxesGlyph` (inherits from `Geom`, `ggproto`, `gg`) of length 7.

An object of class `GeomSerialaxesHist` (inherits from `GeomBar_`, `GeomBar`, `GeomRect`, `Geom`, `ggproto`, `gg`) of length 2.

An object of class `GeomSerialaxesQuantile` (inherits from `GeomPath`, `Geom`, `ggproto`, `gg`) of length 4.

An object of class `GeomSerialaxes` (inherits from `GeomPath`, `Geom`, `ggproto`, `gg`) of length 3.

---

geom_density_   *More general smoothed density estimates*

Description

Computes and draws kernel density estimate. Compared with `geom_density()`, it provides more general cases that accepting `x` and `y`. See details

Usage

```
geom_density_(
  mapping = NULL,
  data = NULL,
  stat = "density_",
  position = "identity_",
  ...,
  scale.x = NULL,
  scale.y = c("data", "group", "variable"),
  as.mix = FALSE,
  positive = TRUE,
  prop = 0.9,
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE
)

stat_density_(
  mapping = NULL,
  data = NULL,
  geom = "density_",
  position = "stack_",
  ...,
  bw = "nrd0",
  adjust = 1,
  kernel = "gaussian",
  n = 512,
  trim = FALSE,
  na.rm = FALSE,
```

```
    orientation = NA,
    show.legend = NA,
    inherit.aes = TRUE
)
```

Arguments

mapping
: Set of aesthetic mappings created by [aes()] or [aes_()]. If specified and inherit.aes = TRUE (the default), it is combined with the default mapping at the top level of the plot. You must supply mapping if there is no plot mapping.

data
: The data to be displayed in this layer. There are three options:

  If NULL, the default, the data is inherited from the plot data as specified in the call to [ggplot()].

  A data.frame, or other object, will override the plot data. All objects will be fortified to produce a data frame. See [fortify()] for which variables will be created.

  A function will be called with a single argument, the plot data. The return value must be a data.frame, and will be used as the layer data. A function can be created from a formula (e.g. ~ head(.x,10)).

stat
: Use to override the default connection between geom_density and stat_density.

position
: Position adjustment, either as a string, or the result of a call to a position adjustment function.

...
: Other arguments passed on to [layer()]. These are often aesthetics, used to set an aesthetic to a fixed value, like colour = "red" or size = 3. They may also be parameters to the paired geom/stat.

scale.x
: A sorted length 2 numerical vector representing the range of the whole data will be scaled to. The default value is (0, 1).

scale.y
: one of data and group to specify.

Type	Description
data (default)	The density estimates are scaled by the whole data set
group	The density estimates are scaled by each group

: If the scale.y is data, it is meaningful to compare the density (shape and area) across all groups; else it is only meaningful to compare the density within each group. See details.

as.mix
: Logical. Within each group, if TRUE, the sum of the density estimate area is mixed and scaled to maximum 1. The area of each subgroup (in general, within each group one color represents one subgroup) is proportional to the count; if FALSE the area of each subgroup is the same, with maximum 1. See details.

positive
: If y is set as the density estimate, where the smoothed curved is faced to, right ('positive') or left ('negative') as vertical layout; up ('positive') or down ('negative') as horizontal layout?

prop
: adjust the proportional maximum height of the estimate (density, histogram, ...).

na.rm
: If FALSE, the default, missing values are removed with a warning. If TRUE, missing values are silently removed.

orientation	The orientation of the layer. The default (NA) automatically determines the orientation from the aesthetic mapping. In the rare event that this fails it can be given explicitly by setting orientation to either "x" or "y". See the *Orientation* section for more detail.
show.legend	logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes. It can also be a named logical vector to finely select the aesthetics to display.
inherit.aes	If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. borders().
geom	Use to override the default connection between geom_density and stat_density.
bw	The smoothing bandwidth to be used. If numeric, the standard deviation of the smoothing kernel. If character, a rule to choose the bandwidth, as listed in stats::bw.nrd().
adjust	A multiplicate bandwidth adjustment. This makes it possible to adjust the bandwidth while still using the a bandwidth estimator. For example, adjust = 1/2 means use half of the default bandwidth.
kernel	Kernel. See list of available kernels in density().
n	number of equally spaced points at which the density is to be estimated, should be a power of two, see density() for details
trim	If FALSE, the default, each density is computed on the full range of the data. If TRUE, each density is computed over the range of that group: this typically means the estimated x values will not line-up, and hence you won't be able to stack density values. This parameter only matters if you are displaying multiple densities in one plot or if you are manually adjusting the scale limits.

Details

The x (or y) is a group variable (categorical) and y (or x) is the target variable (numerical) to be plotted. If only one of x or y is provided, it will treated as a target variable and ggplot2::geom_density will be executed.

There are four combinations of scale.y and as.mix.

scale.y = **"group"** and as.mix = **FALSE** The density estimate area of each subgroup (represented by each color) within the same group is the same.

scale.y = **"group"** and as.mix = **TRUE** The density estimate area of each subgroup (represented by each color) within the same group is proportional to its own counts.

scale.y = **"data"** and as.mix = **FALSE** The sum of density estimate area of all groups is scaled to maximum of 1. and the density area for each group is proportional to the its count. Within each group, the area of each subgroup is the same.

scale.y = **"data"** and as.mix = **TRUE** The sum of density estimate area of all groups is scaled to maximum of 1 and the area of each subgroup (represented by each color) is proportional to its own count.

See vignettes[https://great-northern-diver.github.io/ggmulti/articles/histogram-density-.html] for more intuitive explanation.

Orientation

This geom treats each axis differently and, thus, can thus have two orientations. Often the orientation is easy to deduce from a combination of the given mappings and the types of positional scales in use. Thus, ggplot2 will by default try to guess which orientation the layer should have. Under rare circumstances, the orientation is ambiguous and guessing may fail. In that case the orientation can be specified directly using the `orientation` parameter, which can be either `"x"` or `"y"`. The value gives the axis that the geom should run along, `"x"` being the default orientation you would expect for the geom.

Examples

```
if(require(dplyr)) {
  mpg %>%
    dplyr::filter(drv != "f") %>%
    ggplot(mapping = aes(x = drv, y = cty, fill = factor(cyl))) +
    geom_density_(alpha = 0.1)

  # only `x` or `y` is provided
  # that would be equivalent to call function `geom_density()`
  diamonds %>%
    dplyr::sample_n(500) %>%
    ggplot(mapping = aes(x = price)) +
    geom_density_()

  # density and boxplot
  # set the density estimate on the left
  mpg %>%
    dplyr::filter(drv != "f") %>%
    ggplot(mapping = aes(x = drv, y = cty,
                         fill = factor(cyl))) +
    geom_density_(alpha = 0.1,
                  scale.y = "group",
                  as.mix = FALSE,
                  positive = FALSE) +
    geom_boxplot()

  # x as density
  set.seed(12345)
  suppressWarnings(
    diamonds %>%
      dplyr::sample_n(500) %>%
      ggplot(mapping = aes(x = price, y = cut, fill = color)) +
      geom_density_(orientation = "x", prop = 0.25,
                    position = "stack_",
                    scale.y = "group")
  )
}
```

```
# settings of `scale.y` and `as.mix`

ggplots <- lapply(list(
                         list(scale.y = "data", as.mix = TRUE),
                         list(scale.y = "data", as.mix = FALSE),
                         list(scale.y = "group", as.mix = TRUE),
                         list(scale.y = "group", as.mix = FALSE)
                       ),
                     function(vars) {
                       scale.y <- vars[["scale.y"]]
                       as.mix <- vars[["as.mix"]]
                       ggplot(mpg,
                             mapping = aes(x = drv, y = cty, fill = factor(cyl))) +
                         geom_density_(alpha = 0.1, scale.y = scale.y, as.mix = as.mix) +
                         labs(title = paste("scale.y =", scale.y),
                               subtitle = paste("as.mix =", as.mix))
                     })
suppressWarnings(
  gridExtra::grid.arrange(grobs = ggplots)
)
```

---

geom_hist_   *More general histogram*

Description

More general histogram (geom_histogram) or bar plot (geom_bar). Both x and y could be accommodated. See details

Usage

```
geom_hist_(
  mapping = NULL,
  data = NULL,
  stat = "hist_",
  position = "stack_",
  ...,
  scale.x = NULL,
  scale.y = c("data", "group", "variable"),
  as.mix = FALSE,
  binwidth = NULL,
  bins = NULL,
  positive = TRUE,
  prop = 0.9,
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE
```

```
)
geom_histogram_(
  mapping = NULL,
  data = NULL,
  stat = "bin_",
  position = "stack_",
  ...,
  scale.x = NULL,
  scale.y = c("data", "group"),
  as.mix = FALSE,
  positive = TRUE,
  prop = 0.9,
  binwidth = NULL,
  bins = NULL,
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE
)

geom_bar_(
  mapping = NULL,
  data = NULL,
  stat = "count_",
  position = "stack_",
  ...,
  scale.x = NULL,
  scale.y = c("data", "group"),
  positive = TRUE,
  prop = 0.9,
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE
)

stat_hist_(
  mapping = NULL,
  data = NULL,
  geom = "bar_",
  position = "stack_",
  ...,
  binwidth = NULL,
  bins = NULL,
  center = NULL,
  boundary = NULL,
  breaks = NULL,
```

```
  closed = c("right", "left"),
  pad = FALSE,
  width = NULL,
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE
)

stat_bin_(
  mapping = NULL,
  data = NULL,
  geom = "bar_",
  position = "stack_",
  ...,
  binwidth = NULL,
  bins = NULL,
  center = NULL,
  boundary = NULL,
  breaks = NULL,
  closed = c("right", "left"),
  pad = FALSE,
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE
)

stat_count_(
  mapping = NULL,
  data = NULL,
  geom = "bar_",
  position = "stack_",
  ...,
  width = NULL,
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE
)
```

Arguments

mapping   Set of aesthetic mappings created by [aes()](#) or [aes_()](#). If specified and inherit.aes
               = TRUE (the default), it is combined with the default mapping at the top level of
               the plot. You must supply mapping if there is no plot mapping.

data   The data to be displayed in this layer. There are three options:

               If NULL, the default, the data is inherited from the plot data as specified in the

	call to `ggplot()`.
	A `data.frame`, or other object, will override the plot data. All objects will be fortified to produce a data frame. See `fortify()` for which variables will be created.
	A `function` will be called with a single argument, the plot data. The return value must be a `data.frame`, and will be used as the layer data. A `function` can be created from a `formula` (e.g. `~ head(.x,10)`).
position	Position adjustment, either as a string, or the result of a call to a position adjustment function. Function geom_hist_ and geom_histogram_ understand `stack_` (stacks bars on top of each other), or `dodge_` and `dodge2_` (overlapping objects side-to-side) instead of `stack`, `dodge` or `dodge2`
...	Other arguments passed on to `layer()`. These are often aesthetics, used to set an aesthetic to a fixed value, like `colour = "red"` or `size = 3`. They may also be parameters to the paired geom/stat.
scale.x	A sorted length 2 numerical vector representing the range of the whole data will be scaled to. The default value is (0, 1).
scale.y	one of `data` and `group` to specify.

Type	Description
data (default)	The density estimates are scaled by the whole data set
group	The density estimates are scaled by each group

	If the `scale.y` is `data`, it is meaningful to compare the density (shape and area) across all groups; else it is only meaningful to compare the density within each group. See details.
as.mix	Logical. Within each group, if `TRUE`, the sum of the density estimate area is mixed and scaled to maximum 1. The area of each subgroup (in general, within each group one color represents one subgroup) is proportional to the count; if `FALSE` the area of each subgroup is the same, with maximum 1. See details.
binwidth	The width of the bins. Can be specified as a numeric value or as a function that calculates width from unscaled x. Here, "unscaled x" refers to the original x values in the data, before application of any scale transformation. When specifying a function along with a grouping structure, the function will be called once per group. The default is to use the number of bins in `bins`, covering the range of the data. You should always override this value, exploring multiple widths to find the best to illustrate the stories in your data.
	The bin width of a date variable is the number of days in each time; the bin width of a time variable is the number of seconds.
bins	Number of bins. Overridden by `binwidth`. Defaults to 30.
positive	If y is set as the density estimate, where the smoothed curved is faced to, right ('positive') or left ('negative') as vertical layout; up ('positive') or down ('negative') as horizontal layout?
prop	adjust the proportional maximum height of the estimate (density, histogram, ...).
na.rm	If `FALSE`, the default, missing values are removed with a warning. If `TRUE`, missing values are silently removed.

orientation	The orientation of the layer. The default (NA) automatically determines the orientation from the aesthetic mapping. In the rare event that this fails it can be given explicitly by setting orientation to either "x" or "y". See the *Orientation* section for more detail.
show.legend	logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes. It can also be a named logical vector to finely select the aesthetics to display.
inherit.aes	If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. borders().
geom, stat	Use to override the default connection between geom_hist_()/geom_histogram_()/geom_bar_() and stat_hist_()/stat_bin_()/stat_count_().
center	bin position specifiers. Only one, center or boundary, may be specified for a single plot. center specifies the center of one of the bins. boundary specifies the boundary between two bins. Note that if either is above or below the range of the data, things will be shifted by the appropriate integer multiple of binwidth. For example, to center on integers use binwidth = 1 and center = 0, even if 0 is outside the range of the data. Alternatively, this same alignment can be specified with binwidth = 1 and boundary = 0.5, even if 0.5 is outside the range of the data.
boundary	bin position specifiers. Only one, center or boundary, may be specified for a single plot. center specifies the center of one of the bins. boundary specifies the boundary between two bins. Note that if either is above or below the range of the data, things will be shifted by the appropriate integer multiple of binwidth. For example, to center on integers use binwidth = 1 and center = 0, even if 0 is outside the range of the data. Alternatively, this same alignment can be specified with binwidth = 1 and boundary = 0.5, even if 0.5 is outside the range of the data.
breaks	Alternatively, you can supply a numeric vector giving the bin boundaries. Overrides binwidth, bins, center, and boundary.
closed	One of "right" or "left" indicating whether right or left edges of bins are included in the bin.
pad	If TRUE, adds empty bins at either end of x. This ensures frequency polygons touch 0. Defaults to FALSE.
width	Bar width. By default, set to 90% of the resolution of the data.

Details

x (or y) is a group variable (categorical) and y (or x) a target variable (numerical) to be plotted. If only one of x or y is provided, it will treated as a target variable and ggplot2::geom_histogram will be executed. Several things should be noticed:

1. If both x and y are given, they can be one discrete one continuous or two discrete. But they cannot be two continuous variables (which one will be considered as a group variable?).

2. geom_hist_ is a wrapper of geom_histogram_ and geom_count_. Suppose the y is our interest (x is the categorical variable), geom_hist_() can accommodate either continuous or discrete y.

While, `geom_histogram_()` only accommodates the continuous y and `geom_bar_()` only accommodates the discrete y.

3. There are four combinations of `scale.y` and `as.mix`.

`scale.y` = **"group"** and `as.mix` = **FALSE** The density estimate area of each subgroup (represented by each color) within the same group is the same.

`scale.y` = **"group"** and `as.mix` = **TRUE** The density estimate area of each subgroup (represented by each color) within the same group is proportional to its own counts.

`scale.y` = **"data"** and `as.mix` = **FALSE** The sum of density estimate area of all groups is scaled to maximum of 1. and the density area for each group is proportional to the its count. Within each group, the area of each subgroup is the same.

`scale.y` = **"data"** and `as.mix` = **TRUE** The sum of density estimate area of all groups is scaled to maximum of 1 and the area of each subgroup (represented by each color) is proportional to its own count.

See vignettes[https://great-northern-diver.github.io/ggmulti/articles/histogram-density-.html] for more intuitive explanation. Note that, if it is a grouped bar chart (both x and y are categorical), parameter 'as.mix' is meaningless.

Orientation

This geom treats each axis differently and, thus, can thus have two orientations. Often the orientation is easy to deduce from a combination of the given mappings and the types of positional scales in use. Thus, ggplot2 will by default try to guess which orientation the layer should have. Under rare circumstances, the orientation is ambiguous and guessing may fail. In that case the orientation can be specified directly using the `orientation` parameter, which can be either `"x"` or `"y"`. The value gives the axis that the geom should run along, `"x"` being the default orientation you would expect for the geom.

Examples

```
if(require(dplyr) && require(tidyr)) {

  # histogram
  p0 <- mpg %>%
    dplyr::filter(manufacturer %in% c("dodge", "ford", "toyota", "volkswagen")) %>%
    ggplot(mapping = aes(x = manufacturer, y = cty))
  p0 + geom_hist_()

  ## set position
  #### default is "stack_"
  p0 + geom_hist_(mapping = aes(fill = fl))
  #### "dodge_"
  p0 + geom_hist_(position = "dodge_",
                  mapping = aes(fill = fl))
  #### "dodge2_"
```

```
    p0 + geom_hist_(position = "dodge2_",
                    mapping = aes(fill = fl))

    # bar chart
    mpg %>%
      ggplot(mapping = aes(x = drv, y = class)) +
      geom_hist_(orientation = "y")

    # scale.y as "group"
    p <- iris %>%
      tidyr::pivot_longer(cols = -Species,
                          names_to = "Outer sterile whorls",
                          values_to = "x") %>%
      ggplot(mapping = aes(x = `Outer sterile whorls`,
                           y = x, fill = Species)) +
      stat_hist_(scale.y = "group",
                 prop = 0.6,
                 alpha = 0.5)
    p
    # with density on the left
    p + stat_density_(scale.y = "group",
                      prop = 0.6,
                      alpha = 0.5,
                      positive = FALSE)

    ########### only `x` or `y` is provided ###########
    # that would be equivalent to call function
    # `geom_histogram()` or `geom_bar()`
    ### histogram
    diamonds %>%
      dplyr::sample_n(500) %>%
      ggplot(mapping = aes(x = price)) +
      geom_hist_()
    ### bar chart
    diamonds %>%
      dplyr::sample_n(500) %>%
      ggplot(mapping = aes(x = cut)) +
      geom_hist_()
}
```

geom_image_glyph   *Add image glyphs on scatter plot*

Description

Each point glyph can be an image (png, jpeg, etc) object.

Usage

```
geom_image_glyph(
```

```
    mapping = NULL,
    data = NULL,
    stat = "identity",
    position = "identity",
    ...,
    images,
    imagewidth = 1.2,
    imageheight = 0.9,
    interpolate = TRUE,
    na.rm = FALSE,
    show.legend = NA,
    inherit.aes = TRUE
)
```

Arguments

mapping	Set of aesthetic mappings created by [aes()](#) or [aes_()](#). If specified and `inherit.aes` = TRUE (the default), it is combined with the default mapping at the top level of the plot. You must supply `mapping` if there is no plot mapping.
data	The data to be displayed in this layer. There are three options:
	If NULL, the default, the data is inherited from the plot data as specified in the call to [ggplot()](#).
	A `data.frame`, or other object, will override the plot data. All objects will be fortified to produce a data frame. See [fortify()](#) for which variables will be created.
	A `function` will be called with a single argument, the plot data. The return value must be a `data.frame`, and will be used as the layer data. A `function` can be created from a `formula` (e.g. `~ head(.x,10)`).
stat	The statistical transformation to use on the data for this layer, as a string.
position	Position adjustment, either as a string, or the result of a call to a position adjustment function.
...	Other arguments passed on to [layer()](#). These are often aesthetics, used to set an aesthetic to a fixed value, like `colour = "red"` or `size = 3`. They may also be parameters to the paired geom/stat.
images	a list of images (a raster object, bitmap image). If not provided, a point visual (geom_point()) will be displayed.
imagewidth	Numerical; width of image
imageheight	Numerical; height of image
interpolate	A logical value indicating whether to linearly interpolate the image (the alternative is to use nearest-neighbour interpolation, which gives a more blocky result). See [rasterGrob](#).
na.rm	If FALSE, the default, missing values are removed with a warning. If TRUE, missing values are silently removed.
show.legend	logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes. It can also be a named logical vector to finely select the aesthetics to display.

inherit.aes   If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. borders().

Value

a geom layer

Aesthetics

geom_...._glyph() understands the following aesthetics (required aesthetics are in bold):

- **x**
- **y**
- alpha
- colour
- fill
- group
- size
- linetype
- shape
- stroke

The size unit is cm

Note that the shape and stroke do not have real meanings unless the essential argument images is missing. If so, a point visual will be displayed with corresponding shape and stroke.

geom_polygon_glyph   *Add polygon glyphs on scatter plot*

Description

Each point glyph can be a polygon object. We provide some common polygon coords in polygon_glyph.
Also, users can customize their own polygons.

Usage

```
geom_polygon_glyph(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  position = "identity",
  ...,
  polygon_x,
```

```
    polygon_y,
    linewidth = 1,
    na.rm = FALSE,
    show.legend = NA,
    inherit.aes = TRUE
)
```

Arguments

mapping	Set of aesthetic mappings created by [aes()](aes()) or [aes_()](aes_()). If specified and inherit.aes = TRUE (the default), it is combined with the default mapping at the top level of the plot. You must supply mapping if there is no plot mapping.
data	The data to be displayed in this layer. There are three options:
	If NULL, the default, the data is inherited from the plot data as specified in the call to ggplot().
	A data.frame, or other object, will override the plot data. All objects will be fortified to produce a data frame. See fortify() for which variables will be created.
	A function will be called with a single argument, the plot data. The return value must be a data.frame, and will be used as the layer data. A function can be created from a formula (e.g. ~ head(.x,10)).
stat	The statistical transformation to use on the data for this layer, as a string.
position	Position adjustment, either as a string, or the result of a call to a position adjustment function.
...	Other arguments passed on to layer(). These are often aesthetics, used to set an aesthetic to a fixed value, like colour = "red" or size = 3. They may also be parameters to the paired geom/stat.
polygon_x	nested list of x-coordinates of polygons, one list element for each scatterplot point. If not provided, a point visual (geom_point()) will be displayed.
polygon_y	nested list of y-coordinates of polygons, one list element for each scatterplot point. If not provided, a point visual (geom_point()) will be displayed.
linewidth	line width of the "glyph" object
na.rm	If FALSE, the default, missing values are removed with a warning. If TRUE, missing values are silently removed.
show.legend	logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes. It can also be a named logical vector to finely select the aesthetics to display.
inherit.aes	If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. borders().

geom_quantiles   *Add quantile layers on serial axes coordinate*

Description

In ggplot2, geom_quantile() is used to fit a quantile regression to the data and draws the fitted
quantiles with lines. However, geom_quantiles() is mainly used to draw quantile lines on serial
axes. See examples

Usage

```
geom_quantiles(
  mapping = NULL,
  data = NULL,
  stat = "quantile",
  position = "identity",
  ...,
  lineend = "butt",
  linejoin = "round",
  linemitre = 10,
  na.rm = FALSE,
  show.legend = NA,
  inherit.aes = TRUE
)
```

Arguments

mapping   Set of aesthetic mappings created by [aes()](#) or [aes_()](#). If specified and inherit.aes
               = TRUE (the default), it is combined with the default mapping at the top level of
               the plot. You must supply mapping if there is no plot mapping.

data   The data to be displayed in this layer. There are three options:

               If NULL, the default, the data is inherited from the plot data as specified in the
               call to [ggplot()](#).

               A data.frame, or other object, will override the plot data. All objects will be
               fortified to produce a data frame. See [fortify()](#) for which variables will be
               created.

               A function will be called with a single argument, the plot data. The return
               value must be a data.frame, and will be used as the layer data. A function
               can be created from a formula (e.g. ~ head(.x,10)).

stat   Use to override the default connection between geom_quantile and stat_quantile.

position   Position adjustment, either as a string, or the result of a call to a position adjust-
               ment function.

...   Other arguments passed on to [layer()](#). These are often aesthetics, used to set
               an aesthetic to a fixed value, like colour = "red" or size = 3. They may also
               be parameters to the paired geom/stat.

lineend	Line end style (round, butt, square).
linejoin	Line join style (round, mitre, bevel).
linemitre	Line mitre limit (number greater than 1).
na.rm	If FALSE, the default, missing values are removed with a warning. If TRUE, missing values are silently removed.
show.legend	logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes. It can also be a named logical vector to finely select the aesthetics to display.
inherit.aes	If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. borders().

geom_serialaxes_quantile

Examples

```
p <- ggplot(iris,
            mapping = aes(
              Sepal.Length = Sepal.Length,
              Sepal.Width = Sepal.Width,
              Petal.Length = Petal.Length,
              Petal.Width = Petal.Width
            )
  ) +
  geom_path(alpha = 0.2)  +
  coord_serialaxes(scaling = "variable")
p + geom_quantiles(colour = c("red", "green", "blue"),
                   quantiles = c(0.25, 0.5, 0.75),
                   size = 2)
```

---

geom_serialaxes   *Serial axes layer*

Description

Draw a serial axes layer, parallel axes under Cartesian system and radial axes under Polar system. It only takes the "widens" data. Each non-aesthetics component defined in the mapping aes() will be treated as an axis.

Usage

```
geom_serialaxes(
  mapping = NULL,
  data = NULL,
  stat = "serialaxes",
  position = "identity",
  ...,
  axes.sequence = character(0L),
  merge = TRUE,
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE
)

stat_serialaxes(
  mapping = NULL,
  data = NULL,
  geom = "serialaxes",
  position = "identity",
  ...,
  axes.sequence = character(0L),
  merge = TRUE,
  axes.position = NULL,
  scaling = c("data", "variable", "observation", "none"),
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE
)

stat_dotProduct(
  mapping = NULL,
  data = NULL,
  geom = "path",
  position = "identity",
  ...,
  axes.sequence = character(0L),
  merge = TRUE,
  scaling = c("data", "variable", "observation", "none"),
  transform = andrews,
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE
)
```

Arguments

mapping	Set of aesthetic mappings created by [aes()](#) or [aes_()](#). If specified and inherit.aes = TRUE (the default), it is combined with the default mapping at the top level of the plot. You must supply mapping if there is no plot mapping.
data	The data to be displayed in this layer. There are three options: If NULL, the default, the data is inherited from the plot data as specified in the call to [ggplot()](#). A data.frame, or other object, will override the plot data. All objects will be fortified to produce a data frame. See [fortify()](#) for which variables will be created. A function will be called with a single argument, the plot data. The return value must be a data.frame, and will be used as the layer data. A function can be created from a formula (e.g. ~ head(.x,10)).
stat	The statistical transformation to use on the data for this layer, as a string.
position	Position adjustment, either as a string, or the result of a call to a position adjustment function.
...	Other arguments passed on to [layer()](#). These are often aesthetics, used to set an aesthetic to a fixed value, like colour = "red" or size = 3. They may also be parameters to the paired geom/stat.
axes.sequence	A vector to define the axes sequence. In serial axes coordinate, the sequence can be either determined in mapping (function aes()) or by axes.sequence. The only difference is that the mapping aesthetics will omit the duplicated axes (check examples in [geom_serialaxes](#)).
merge	Should axes.sequence be merged with mapping aesthetics as a single mapping uneval object?
na.rm	If FALSE, the default, missing values are removed with a warning. If TRUE, missing values are silently removed.
orientation	The orientation of the layer. The default (NA) automatically determines the orientation from the aesthetic mapping. In the rare event that this fails it can be given explicitly by setting orientation to either "x" or "y". See the *Orientation* section for more detail.
show.legend	logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes. It can also be a named logical vector to finely select the aesthetics to display.
inherit.aes	If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. [borders()](#).
geom	The geometric object to use display the data
axes.position	A numerical vector to determine the axes sequence position; the length should be the same with the length of axes.sequence (or mapping aesthetics, see examples).
scaling	one of data, variable, observation or none (not suggested the layout is the same with data) to specify how the data is scaled.
transform	A transformation function, can be either andrews, legendre or some other customized transformation functions.

Details

The difference between the "lengthens" data and "widens" data can be found in Tidy Data. How to transform one to the other is explained in tidyr

    trim = FALSE,
    na.rm = FALSE,
    orientation = NA,
    show.legend = NA,
    inherit.aes = TRUE
)
```

Arguments

mapping	Set of aesthetic mappings created by [aes()](#) or [aes_()](#). If specified and `inherit.aes` = TRUE (the default), it is combined with the default mapping at the top level of the plot. You must supply `mapping` if there is no plot mapping.
data	The data to be displayed in this layer. There are three options:
	If NULL, the default, the data is inherited from the plot data as specified in the call to [ggplot()](#).
	A `data.frame`, or other object, will override the plot data. All objects will be fortified to produce a data frame. See [fortify()](#) for which variables will be created.
	A `function` will be called with a single argument, the plot data. The return value must be a `data.frame`, and will be used as the layer data. A `function` can be created from a `formula` (e.g. `~ head(.x,10)`).
stat	The statistical transformation to use on the data for this layer, as a string.
position	Position adjustment, either as a string, or the result of a call to a position adjustment function.
...	Other arguments passed on to [layer()](#). These are often aesthetics, used to set an aesthetic to a fixed value, like `colour = "red"` or `size = 3`. They may also be parameters to the paired geom/stat.
axes.sequence	A vector to define the axes sequence. In serial axes coordinate, the sequence can be either determined in mapping (function aes()) or by `axes.sequence`. The only difference is that the `mapping` aesthetics will omit the duplicated axes (check examples in [geom_serialaxes](#)).
merge	Should `axes.sequence` be merged with mapping aesthetics as a single mapping uneval object?
scale.y	one of `data` and `group` to specify.

Type	Description
data (default)	The density estimates are scaled by the whole data set
group	The density estimates are scaled by each group

If the `scale.y` is `data`, it is meaningful to compare the density (shape and area)

	across all groups; else it is only meaningful to compare the density within each group. See details.
as.mix	Logical. Within each group, if TRUE, the sum of the density estimate area is mixed and scaled to maximum 1. The area of each subgroup (in general, within each group one color represents one subgroup) is proportional to the count; if FALSE the area of each subgroup is the same, with maximum 1. See details.
positive	If y is set as the density estimate, where the smoothed curved is faced to, right ('positive') or left ('negative') as vertical layout; up ('positive') or down ('negative') as horizontal layout?
prop	adjust the proportional maximum height of the estimate (density, histogram, ...).
na.rm	If FALSE, the default, missing values are removed with a warning. If TRUE, missing values are silently removed.
orientation	The orientation of the layer. The default (NA) automatically determines the orientation from the aesthetic mapping. In the rare event that this fails it can be given explicitly by setting orientation to either "x" or "y". See the *Orientation* section for more detail.
show.legend	logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes. It can also be a named logical vector to finely select the aesthetics to display.
inherit.aes	If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. borders().
geom	The geometric object to use display the data
axes.position	A numerical vector to determine the axes sequence position; the length should be the same with the length of axes.sequence (or mapping aesthetics, see examples).
scaling	one of data, variable, observation or none (not suggested the layout is the same with data) to specify how the data is scaled.
bw	The smoothing bandwidth to be used. If numeric, the standard deviation of the smoothing kernel. If character, a rule to choose the bandwidth, as listed in stats::bw.nrd().
adjust	A multiplicate bandwidth adjustment. This makes it possible to adjust the bandwidth while still using the a bandwidth estimator. For example, adjust = 1/2 means use half of the default bandwidth.
kernel	Kernel. See list of available kernels in density().
n	number of equally spaced points at which the density is to be estimated, should be a power of two, see density() for details
trim	If FALSE, the default, each density is computed on the full range of the data. If TRUE, each density is computed over the range of that group: this typically means the estimated x values will not line-up, and hence you won't be able to stack density values. This parameter only matters if you are displaying multiple densities in one plot or if you are manually adjusting the scale limits.

Examples

```
p <- ggplot(iris, mapping = aes(Sepal.Length = Sepal.Length,
                                Sepal.Width = Sepal.Width,
                                Petal.Length = Petal.Length,
                                Petal.Width = Petal.Width,
                                colour = Species,
                                fill = Species)) +
      geom_serialaxes(alpha = 0.2) +
      geom_serialaxes_density(alpha = 0.5) +
      scale_x_continuous(breaks = 1:4,
                         labels = colnames(iris)[-5]) +
      scale_y_continuous(labels = NULL) +
      xlab("variable") +
      ylab("") +
      theme(axis.text.x = element_text(angle = 45, vjust = 0.5))
   p
```

---

geom_serialaxes_glyph   *Add serial axes glyphs on scatter plot*

Description

To visualize high dimensional data on scatterplot. Each point glyph is surrounded by a serial axes (parallel axes or radial axes) object.

Usage

```
geom_serialaxes_glyph(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  position = "identity",
  ...,
  serialaxes.data,
  axes.sequence = character(0L),
  scaling = c("data", "variable", "observation", "none"),
  axes.layout = c("parallel", "radial"),
  andrews = FALSE,
  show.axes = FALSE,
  show.enclosing = FALSE,
  linewidth = 1,
  axescolour = "black",
  bboxcolour = "black",
  na.rm = FALSE,
```

```
    show.legend = NA,
    inherit.aes = TRUE
)
```

Arguments

mapping	Set of aesthetic mappings created by [aes()](#) or [aes_()](#). If specified and `inherit.aes` = TRUE (the default), it is combined with the default mapping at the top level of the plot. You must supply mapping if there is no plot mapping.
data	The data to be displayed in this layer. There are three options:
	If NULL, the default, the data is inherited from the plot data as specified in the call to [ggplot()](#).
	A `data.frame`, or other object, will override the plot data. All objects will be fortified to produce a data frame. See [fortify()](#) for which variables will be created.
	A `function` will be called with a single argument, the plot data. The return value must be a `data.frame`, and will be used as the layer data. A function can be created from a `formula` (e.g. ~ head(.x,10)).
stat	The statistical transformation to use on the data for this layer, as a string.
position	Position adjustment, either as a string, or the result of a call to a position adjustment function.
...	Other arguments passed on to [layer()](#). These are often aesthetics, used to set an aesthetic to a fixed value, like colour = "red" or size = 3. They may also be parameters to the paired geom/stat.
serialaxes.data	
	a serial axes numerical data set. If not provided, a point visual (geom_point()) will be displayed.
axes.sequence	A vector to define the axes sequence. In serial axes coordinate, the sequence can be either determined in mapping (function aes()) or by axes.sequence. The only difference is that the mapping aesthetics will omit the duplicated axes (check examples in [geom_serialaxes](#)).
scaling	one of data, variable, observation or none (not suggested the layout is the same with data) to specify how the data is scaled.
axes.layout	either "radial" or "parallel"
andrews	Logical; Andrew's plot (a Fourier transformation)
show.axes	boolean to indicate whether axes should be shown or not
show.enclosing	boolean to indicate whether enclosing should be shown or not
linewidth	line width of the "glyph" object
axescolour	axes color
bboxcolour	bounding box color
na.rm	If FALSE, the default, missing values are removed with a warning. If TRUE, missing values are silently removed.

show.legend	logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes. It can also be a named logical vector to finely select the aesthetics to display.
inherit.aes	If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. borders().

Value

a geom layer

Aesthetics

geom_..._glyph() understands the following aesthetics (required aesthetics are in bold):

- **x**
- **y**
- alpha
- colour
- fill
- group
- size
- linetype
- shape
- stroke

The size unit is cm

Note that the shape and stroke do not have real meanings unless the essential argument serialaxes.data is missing. If so, a point visual will be displayed with corresponding shape and stroke.

```
# serial axes glyph
p <- ggplot(data = iris,
            mapping = aes(x = Sepal.Length, y = Sepal.Width, colour = Species)) +
  geom_serialaxes_glyph(serialaxes.data = iris[, -5],
                        axes.layout = "radial")
p
```

geom_serialaxes_hist | *Histogram for "widens" data under serial axes coordinate*

Description

Computes and draws histogram on serial axes coordinate for each non-aesthetics component defined in the mapping aes().

Usage

```
geom_serialaxes_hist(
  mapping = NULL,
  data = NULL,
  stat = "serialaxes_hist",
  position = "stack_",
  ...,
  axes.sequence = character(0L),
  axes.position = NULL,
  merge = TRUE,
  scale.y = c("data", "group"),
  as.mix = TRUE,
  positive = TRUE,
  prop = 0.9,
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE
)

stat_serialaxes_hist(
  mapping = NULL,
  data = NULL,
  geom = "serialaxes_hist",
  position = "stack_",
  ...,
  axes.sequence = character(0L),
  scaling = c("data", "variable", "observation", "none"),
  axes.position = NULL,
  binwidth = NULL,
  bins = NULL,
  center = NULL,
  boundary = NULL,
  breaks = NULL,
  closed = c("right", "left"),
  pad = FALSE,
  width = NULL,
  na.rm = FALSE,
```

```
    orientation = NA,
    show.legend = NA,
    inherit.aes = TRUE
)
```

Arguments

mapping	Set of aesthetic mappings created by [aes()](#) or [aes_()](#). If specified and inherit.aes = TRUE (the default), it is combined with the default mapping at the top level of the plot. You must supply mapping if there is no plot mapping.
data	The data to be displayed in this layer. There are three options:
	If NULL, the default, the data is inherited from the plot data as specified in the call to [ggplot()](#).
	A data.frame, or other object, will override the plot data. All objects will be fortified to produce a data frame. See [fortify()](#) for which variables will be created.
	A function will be called with a single argument, the plot data. The return value must be a data.frame, and will be used as the layer data. A function can be created from a formula (e.g. ~ head(.x,10)).
stat	The statistical transformation to use on the data for this layer, as a string.
position	Position adjustment, either as a string, or the result of a call to a position adjustment function.
...	Other arguments passed on to [layer()](#). These are often aesthetics, used to set an aesthetic to a fixed value, like colour = "red" or size = 3. They may also be parameters to the paired geom/stat.
axes.sequence	A vector to define the axes sequence. In serial axes coordinate, the sequence can be either determined in mapping (function aes()) or by axes.sequence. The only difference is that the mapping aesthetics will omit the duplicated axes (check examples in [geom_serialaxes](#)).
axes.position	A numerical vector to determine the axes sequence position; the length should be the same with the length of axes.sequence (or mapping aesthetics, see examples).
merge	Should axes.sequence be merged with mapping aesthetics as a single mapping uneval object?
scale.y	one of data and group to specify.

Type	Description
data (default)	The density estimates are scaled by the whole data set
group	The density estimates are scaled by each group

	If the scale.y is data, it is meaningful to compare the density (shape and area) across all groups; else it is only meaningful to compare the density within each group. See details.
as.mix	Logical. Within each group, if TRUE, the sum of the density estimate area is mixed and scaled to maximum 1. The area of each subgroup (in general, within

each group one color represents one subgroup) is proportional to the count; if `FALSE` the area of each subgroup is the same, with maximum 1. See details.

positive	If y is set as the density estimate, where the smoothed curved is faced to, right ('positive') or left ('negative') as vertical layout; up ('positive') or down ('negative') as horizontal layout?
prop	adjust the proportional maximum height of the estimate (density, histogram, ...).
na.rm	If `FALSE`, the default, missing values are removed with a warning. If `TRUE`, missing values are silently removed.
orientation	The orientation of the layer. The default (NA) automatically determines the orientation from the aesthetic mapping. In the rare event that this fails it can be given explicitly by setting `orientation` to either `"x"` or `"y"`. See the *Orientation* section for more detail.
show.legend	logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. `FALSE` never includes, and `TRUE` always includes. It can also be a named logical vector to finely select the aesthetics to display.
inherit.aes	If `FALSE`, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. `borders()`.
geom	The geometric object to use display the data
scaling	one of `data`, `variable`, `observation` or `none` (not suggested the layout is the same with `data`) to specify how the data is scaled.
binwidth	The width of the bins. Can be specified as a numeric value or as a function that calculates width from unscaled x. Here, "unscaled x" refers to the original x values in the data, before application of any scale transformation. When specifying a function along with a grouping structure, the function will be called once per group. The default is to use the number of bins in `bins`, covering the range of the data. You should always override this value, exploring multiple widths to find the best to illustrate the stories in your data. The bin width of a date variable is the number of days in each time; the bin width of a time variable is the number of seconds.
bins	Number of bins. Overridden by `binwidth`. Defaults to 30.
center	bin position specifiers. Only one, `center` or boundary, may be specified for a single plot. `center` specifies the center of one of the bins. boundary specifies the boundary between two bins. Note that if either is above or below the range of the data, things will be shifted by the appropriate integer multiple of `binwidth`. For example, to center on integers use `binwidth = 1` and `center = 0`, even if `0` is outside the range of the data. Alternatively, this same alignment can be specified with `binwidth = 1` and `boundary = 0.5`, even if `0.5` is outside the range of the data.
boundary	bin position specifiers. Only one, `center` or boundary, may be specified for a single plot. `center` specifies the center of one of the bins. boundary specifies the boundary between two bins. Note that if either is above or below the range of the data, things will be shifted by the appropriate integer multiple of `binwidth`. For example, to center on integers use `binwidth = 1` and `center = 0`, even if `0` is outside the range of the data. Alternatively, this same alignment can be specified

with `binwidth = 1` and `boundary = 0.5`, even if `0.5` is outside the range of the data.

breaks   Alternatively, you can supply a numeric vector giving the bin boundaries. Over-
                      rides `binwidth`, `bins`, `center`, and `boundary`.

closed   One of `"right"` or `"left"` indicating whether right or left edges of bins are
                      included in the bin.

pad   If `TRUE`, adds empty bins at either end of x. This ensures frequency polygons
                      touch 0. Defaults to `FALSE`.

width   Bar width. By default, set to 90% of the resolution of the data.

geom_serialaxes_quantile
                          Quantile layer for serial axes coordinate

---

Description

Draw a quantile layer for serial axes coordinate. Don't be confused with `geom_quantile()` which
is a quantile regression. See examples.

Usage

```
geom_serialaxes_quantile(
  mapping = NULL,
  data = NULL,
  stat = "serialaxes",
  position = "identity",
  ...,
  axes.sequence = character(0L),
  merge = TRUE,
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE
)

stat_serialaxes_quantile(
  mapping = NULL,
  data = NULL,
  geom = "serialaxes_quantile",
  position = "identity",
  ...,
  axes.sequence = character(0L),
  merge = TRUE,
  quantiles = seq(0, 1, 0.25),
  scaling = c("data", "variable", "observation", "none"),
  axes.position = NULL,
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE
)
```

Arguments

mapping	Set of aesthetic mappings created by [aes()](#) or [aes_()](#). If specified and inherit.aes = TRUE (the default), it is combined with the default mapping at the top level of the plot. You must supply mapping if there is no plot mapping.
data	The data to be displayed in this layer. There are three options:
	If NULL, the default, the data is inherited from the plot data as specified in the call to [ggplot()](#).
	A data.frame, or other object, will override the plot data. All objects will be fortified to produce a data frame. See [fortify()](#) for which variables will be created.
	A function will be called with a single argument, the plot data. The return value must be a data.frame, and will be used as the layer data. A function can be created from a formula (e.g. ~ head(.x,10)).
stat	The statistical transformation to use on the data for this layer, as a string.

position   Position adjustment, either as a string, or the result of a call to a position adjustment function.

...   Other arguments passed on to `layer()`. These are often aesthetics, used to set an aesthetic to a fixed value, like colour = "red" or size = 3. They may also be parameters to the paired geom/stat.

axes.sequence   A vector to define the axes sequence. In serial axes coordinate, the sequence can be either determined in mapping (function aes()) or by axes.sequence. The only difference is that the mapping aesthetics will omit the duplicated axes (check examples in `geom_serialaxes`).

merge   Should axes.sequence be merged with mapping aesthetics as a single mapping uneval object?

na.rm   If FALSE, the default, missing values are removed with a warning. If TRUE, missing values are silently removed.

orientation   The orientation of the layer. The default (NA) automatically determines the orientation from the aesthetic mapping. In the rare event that this fails it can be given explicitly by setting orientation to either "x" or "y". See the *Orientation* section for more detail.

show.legend   logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes. It can also be a named logical vector to finely select the aesthetics to display.

inherit.aes   If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. `borders()`.

geom   The geometric object to use display the data

quantiles   numeric vector of probabilities with values in [0,1]. (Values up to 2e-14 outside that range are accepted and moved to the nearby endpoint.)

scaling   one of data, variable, observation or none (not suggested the layout is the same with data) to specify how the data is scaled.

axes.position   A numerical vector to determine the axes sequence position; the length should be the same with the length of axes.sequence (or mapping aesthetics, see examples).

`geom_density_`, `geom_serialaxes`, `geom_serialaxes_density`, `geom_serialaxes_hist`

Examples

```
# lower quantile, median and upper quantile
p <- ggplot(iris, mapping = aes(Sepal.Length = Sepal.Length,
                                Sepal.Width = Sepal.Width,
                                Petal.Length = Petal.Length,
                                Petal.Width = Petal.Width)) +
      geom_serialaxes(stat = "dotProduct") +
      geom_serialaxes_quantile(stat = "dotProduct",
                               quantiles = c(0.25, 0.5, 0.75),
```

```
                              colour = c("red", "blue", "green"), size = 2)
    p
```

---

get_scaledData   *scale data*

Description

It is mainly used in serial axes

Usage

```
get_scaledData(
  data,
  sequence = NULL,
  scaling = c("data", "variable", "observation", "none"),
  displayOrder = NULL,
  reserve = FALSE,
  as.data.frame = FALSE
)
```

Arguments

data	A data frame
sequence	vector with variable names that defines the axes sequence. If NULL, it will be set as the column names automatically.
scaling	one of data, variable, observation or none (not suggested the layout is the same with data) to specify how the data is scaled.
displayOrder	the order of the display
reserve	If TRUE, return the variables not shown in sequence as well; else only return the variables defined in sequence.
as.data.frame	Return a matrix or a data.frame

NBAstats2021   *NBA 30 Teams Statistics in 20-21 Regular Season*

Description

A dataset containing the statistics (e.g. Points Per Game, Average Field Goals Made, etc) of 30 NBA Teams in 2020-2021 regular season

Format

A data frame with 30 rows (teams) and 42 variables:

Team Team Names.

CONF Factor; Conference of Teams (West or East).

DIV Factor; Division of Teams.

Playoff Factor; Whether Teams are in (0 or 1) Playoffs.

PTS Points Per Game.

FGM Average Field Goals Made.

FGA Average Field Goals Attempted.

FG% Field Goal Percentage.

3PM Average 3-Point Field Goals Made.

3PA Average 3-Point Field Goals Attempted.

3P% 3-Point Field Goal Percentage.

FTM Average Free Throws Made.

FTA Average Free Throws Attempted.

FT% Free Throw Percentage.

OR Offensive Rebounds Per Game.

DR Defensive Rebounds Per Game.

REB Rebounds Per Game.

AST Assists Per Game.

STL Steals Per Game.

BLK Blocks Per Game.

TO Turnovers Per Game.

PF Fouls Per Game.

OPTS Opponent Points Per Game.

OFGM Opponent Average Field Goals Made.

OFGA Opponent Average Field Goals Attempted.

OFG% Opponent Field Goal Percentage.

O3PM Opponent Average 3-Point Field Goals Made.

O3PA Opponent Average 3-Point Field Goals Attempted.

O3P% Opponent 3-Point Field Goal Percentage.

OFTM Opponent Average Free Throws Made.

OFTA Opponent Average Free Throws Attempted.

OFT% Opponent Free Throw Percentage.

OOR Opponent Offensive Rebounds Per Game.

ODR Opponent Defensive Rebounds Per Game.

OREB Opponent Rebounds Per Game.

OAST Opponent Assists Per Game.

OSTL Opponent Steals Per Game.

OBLK Opponent Blocks Per Game.

OTO Opponent Turnovers Per Game.

OPF Opponent Fouls Per Game.

Win Win Games in Regular Season.

Lose Loss Games in Regular Season.

               y=(y_airplane + 1)/2)
  grid.newpage()
  grid.polygon(x=(x_maple + 1)/2,
               y=(y_maple + 1)/2)
}
```

Position-ggproto   *Base Position ggproto classes for ggplot2*

Description

All position_ functions (like position_dodge) return a Position object (like PositionDodge). The Position object is responsible for adjusting the position of overlapping geoms. The way that the position_ functions work is slightly different from the geom_ and stat_ functions, because a position_ function actually "instantiates" the Position object by creating a descendant, and returns that. Each of the Position objects is a ggproto object, descended from the top-level Position.

Usage

```
PositionDodge_

PositionDodge2_

PositionIdentity_

PositionStack_

PositionFill_
```

Format

An object of class PositionDodge_ (inherits from PositionDodge, Position, ggproto, gg) of length 2.

An object of class PositionDodge2_ (inherits from PositionDodge2, PositionDodge, Position, ggproto, gg) of length 2.

An object of class PositionIdentity_ (inherits from PositionIdentity, Position, ggproto, gg) of length 3.

An object of class PositionStack_ (inherits from PositionStack, Position, ggproto, gg) of length 3.

An object of class PositionFill_ (inherits from PositionStack_, PositionStack, Position, ggproto, gg) of length 2.

---

position_dodge_   *Dodge overlapping objects side-to-side*

Description

Dodging preserves the vertical position of an geom while adjusting the horizontal position. position_dodge_() dodges bars side by side but conditional on locations.

Usage

```
position_dodge_(width = NULL, preserve = c("total", "single"))

position_dodge2_(
  width = NULL,
  preserve = c("total", "single"),
  padding = 0.1,
  reverse = FALSE
)
```

Arguments

width	Dodging width, when different to the width of the individual elements. This is useful when you want to align narrow geoms with wider geoms. See the examples.
preserve	Should dodging preserve the total width of all elements at a position, or the width of a single element?
padding	Padding between elements at the same position. Elements are shrunk by this proportion to allow space between them. Defaults to 0.1.
reverse	If TRUE, will reverse the default stacking order. This is useful if you're rotating both the plot and legend.

Details

It is built based on [position_dodge](#), but used for multiple locations, such as geom_hist_() or geom_density_(). Check examples to see the difference.

See Also

See [geom_hist_](#) and [geom_serialaxes_hist](#) for more examples.

Other position adjustments for multiple locations: [position_identity_](#), [position_stack_](#), [position_fill_](#)

Parent: [position_dodge](#)

Examples

```
if(require(dplyr)) {
p <- iris %>%
  tidyr::pivot_longer(cols = -Species,
                      names_to = "Outer sterile whorls",
                      values_to = "values") %>%
  ggplot(data,
         mapping = aes(x = `Outer sterile whorls`,
                       y = values,
                       fill = Species))

p + geom_hist_(position = position_dodge_())
}
```

```
# all bins are shifted on the left
p +
  geom_hist_(position = position_dodge())
```

---

position_identity_ *Don't adjust position*

Description

Don't adjust position

Usage

```
position_identity_()
```

See Also

Other position adjustments for multiple locations: position_stack_, position_fill_, position_dodge_, position_dodge2_

---

position_stack_ *Stack overlapping objects on top of each another*

Description

position_stack_ stacks bars on top of each other, conditional on locations.

Usage

```
position_stack_(vjust = 1, reverse = FALSE)

position_fill_(vjust = 1, reverse = FALSE)
```

Arguments

vjust   Vertical adjustment for geoms that have a position (like points or lines), not a
                 dimension (like bars or areas). Set to 0 to align with the bottom, 0.5 for the
                 middle, and 1 (the default) for the top.

reverse   If TRUE, will reverse the default stacking order. This is useful if you're rotating
                 both the plot and legend.

Details

It is built based on position_stack, but used for multiple locations, such as geom_hist_ or geom_density_. Rather than stack everything on top of each other, position_stack_ stacks bars based on locations. Check examples to see the difference.

See Also

See geom_hist_, geom_density_, geom_serialaxes_density and geom_serialaxes_hist for more examples.

Other position adjustments for multiple locations: position_identity_, position_dodge_, position_dodge2_

Parent: position_stack

Examples

```
p <- ggplot(iris,
      mapping = aes(Sepal.Length = Sepal.Length,
                    Sepal.Width = Sepal.Width,
                    Petal.Length = Petal.Length,
                    Petal.Width = Petal.Width,
                    colour = Species))
p +
 geom_serialaxes_density(position = position_stack_())

p +
  geom_serialaxes_density(position = position_stack())
```

Stat-ggproto   *Base Stat ggproto classes for ggplot2*

Description

All stat_ functions (like stat_bin()) return a layer that contains a Stat object (like StatBin). The Stat object is responsible for rendering the data in the plot. Each of the Stat objects is a ggproto object, descended from the top-level Stat, and each implements various methods and fields.

Usage

```
StatDensity_

StatHist_

StatBin_
```

StatCount_

StatSerialaxesDensity

StatSerialaxesHist

StatSerialaxes

StatDotProduct

Format

An object of class StatDensity_ (inherits from StatDensity, Stat, ggproto, gg) of length 4.

An object of class StatHist_ (inherits from StatBin, Stat, ggproto, gg) of length 4.

An object of class StatBin_ (inherits from StatHist_, StatBin, Stat, ggproto, gg) of length 2.

An object of class StatCount_ (inherits from StatHist_, StatBin, Stat, ggproto, gg) of length 2.

An object of class StatSerialaxesDensity (inherits from StatDensity, Stat, ggproto, gg) of length 4.

An object of class StatSerialaxesHist (inherits from StatBin, Stat, ggproto, gg) of length 4.

An object of class StatSerialaxes (inherits from Stat, ggproto, gg) of length 6.

An object of class StatDotProduct (inherits from StatSerialaxes, Stat, ggproto, gg) of length 4.
