# Package 'kinship2'

February 10, 2020

Version 1.8.5

<b>Date</b> 2019-5-31
Title Pedigree Functions
<b>Depends</b> R (>= 3.4.0), Matrix, quadprog
Suggests knitr
Imports graphics, stats, methods
Postription  Routines to handle family data with a pedigree object (2014, <doi: 000363105="" 10.1159="">). The initial purpose was to create correlation structures that describe family relationships such as kinship and identity-by-descent, which can be used to model family data in mixed effects models, such as in the coxme function. Also includes a tool for pedigree drawing which is focused on producing compact layouts without intervention. Recent additions include utilities to trim the pedigree object with various criteria, and kinship for the X chromosome.</doi:>

align.po	edigree	Gene	erate	plotti	ing in	forma	tion for	r a pedi	gree	

#### **Description**

Given a pedigree, this function creates helper matrices that descibe the layout of a plot of the pedigree.

## Usage

```
align.pedigree(ped, packed=TRUE, width=10, align=TRUE, hints=ped$hints)
```

## Arguments

packed should the pedigree be compressed, i.e., to allow diagonal lines connecting parents to children in order to have a smaller overall width for the plot.

hints plotting hints for the pedigree. This is a list with components order and spouse,

the second one is optional. If the hints are missing the autohint routine is called to supply an initial guess.

The order component is a numeric vector with one element per subject in the pedigree. It determines the relative order of subjects within a sibship, as well as the relative order of processing for the founder couples. (For this latter, the female founders are ordered as though they were sisters). The spouse component

autohint 3

is a matrix with one row per hinted marriage, usually only a few marriages in a pedigree will need an added hint, for instance reverse the plot order of a husband/wife pair. Each row contains the index of the left spouse, the right hand spouse, and the anchor: 1=left, 2=right, 0=either. Children will preferentially appear under the parents of the anchored spouse.

appear under the parents of the anchored

width for a packed output, the minimum width

align for a packed pedigree, align children under parents (TRUE), to the extent pos-

sible given the page width, or align to to the left margin (FALSE). The latter is

mostly used by internal routines.

#### **Details**

This is an internal routine, used almost exclusively by plot.pedigree. The subservient functions alignped1, alignped2, alignped3, and alignped4 contain the bulk of the computation.

#### Value

a structure with components

n	a vector giving the number of subjects on each horizonal level of the plot
nid	a matrix with one row for each level, giving the numeric id of each subject plotted. (An value of 17 means the 17th subject in the pedigree).
pos	a matrix giving the horizontal position of each plot point
fam	a matrix giving the family id of each plot point. A value of "3" would mean that the two subjects in positions 3 and 4, in the row above, are this subject's parents.
spouse	a matrix with values $1=$ subject plotted to the immediate right is a spouse, $2=$ subject plotted to the immediate right is an inbred spouse, $0=$ not a spouse
twins	optional matrix which will only be present if the pedigree contains twins. It has values $1=$ sibling to the right is a monozygotic twin, $2=$ sibling to the right is a dizygotic twin, $3=$ sibling to the right is a twin of unknown zygosity, $0=$ not a

## See Also

plot.pedigree, autohint

twin

á	autohint	Align a pedigree to print well	

#### **Description**

A pedigree structure can contain a hints object which helps to reorder the pedigree (e.g. left-to-right order of children within family) so as to plot with minimal distortion. This routine is used to create an initial version of the hints. They can then be modified if desired.

4 autohint

#### Usage

```
autohint(ped, hints, packed=TRUE, align=FALSE)
```

#### **Arguments**

ped a pedigree structure

hints optional hints object. Only the order component is used.

packed If TRUE, uniform distance between all individuals at a given level.

align these parameters control the extra effort spent trying to align children underneath

parents, but without making the pedigree too wide. Set to FALSE to speed up

plotting.

#### **Details**

This routine would not normally be called by a user. It moves children within families, so that marriages are on the "edge" of a set children, closest to the spouse. For pedigrees that have only a single connection between two families this simple-minded approach works surprisingly well. For more complex structures hand-tuning of the hints matrix may be required.

The pedigree in the example below is one where rearranging the founders greatly decreases the number of extra connections. When autohint is called with a a vector of numbers as the second argument, the values for the founder females are used to order the founder families left to right across the plot. The values within a sibship are used as the preliminary order of siblings within a family; this may be changed to move one of them to the edge so as to match up with a spouse. The actual values in the vector are not important, only their order.

#### Value

a list containing components order and spouse

#### See Also

pedigree, besthint

## **Examples**

```
data(testped1)
ped1 <- with(testped1, pedigree(id, father, mother, sex))
plot(ped1, cex=.7, symbolsize=.7)

# rearrange some founders
temp <- 1:nrow(testped1)
temp[76] <- .1
temp[77] <- .2
temp[74] <- .3
temp[60] <- .4
temp[30] <- temp[8] + .1
temp[55] <- temp[4] + .1
temp[14] <- temp[3] + .1
ped1$hints <- autohint(ped1, temp)
plot(ped1, cex=.7)</pre>
```

bitSize 5

bitSize

Calculate pedigree bitsize, defined as 2 \* # NonFounders - # Founders

#### **Description**

This is a utility function used in pedigree.shrink()

#### Usage

bitSize(ped)

#### **Arguments**

ped A pedigree object

#### Value

A list with the following components:

bitSize The bitSize of input pedigree

nFounder The number of founders in the pedigree nNonFounder The number of nonfounders in the pedgiree

#### See Also

pedigree.shrink

familycheck

Error check for a family classification

## Description

Given a family id vector, also compute the familial grouping from first principles using the parenting data, and compare the results.

## Usage

```
familycheck(famid, id, father.id, mother.id, newfam)
```

## **Arguments**

famid a vector of family identifiers

id a vector of unique subject identifiers

father.id vector containing the id of the biological father mother.id vector containing the id of the biological mother

newfam the result of a call to makefamid. If this has allready been computed by the user,

adding it as an argument shortens the running time somewhat.

6 familycheck

#### **Details**

The makefamid function is used to create a de novo family id from the parentage data, and this is compared to the family id given in the data.

#### Value

a data frame with one row for each unique family id in the famid argument. Components of the output are

famid the family id, as entered into the data set

n number of subjects in the family

unrelated number of them that appear to be unrelated to anyone else in the entire pedigree

set. This is usually marry-ins with no children (in the pedigree), and if so are

not a problem.

split number of unique "new" family ids. If this is 0, it means that no one in this

"family" is related to anyone else (not good); 1 = everythings is fine; 2+= the family appears to be a set of disjoint trees. Are you missing some of the people?

join number of other families that had a unique famid, but are actually joined to this

one. 0 is the hope. If there are any joins, then an attribute "join" is attached. It will be a matrix with famid as row labels, new-family-id as the columns, and the

number of subjects as entries.

#### See Also

```
makefamid, makekinship
```

#### **Examples**

findAvailAffected 7

findAvailAffected	Find a single person to trim from a pedigree whose is available

## **Description**

Finds one subject from among available non-parents with indicated affection status

#### Usage

```
findAvailAffected(ped, avail, affstatus)
```

## Arguments

ped A pedigree	objects, with	id (subject ID	), findex	(father index)	. mindex (m	nother
----------------	---------------	----------------	-----------	----------------	-------------	--------

index)

avail Vector of availability status (e.g., genotyped) 0/1 or TRUE/FALSE

affstatus Vector of affection status 0/1 or TRUE/FALSE.

## **Details**

When used within pedigree.shrink, this function is called with the first affected indicator, if the affected item in the pedigree is a matrix of multiple affected indicators.

#### Value

A list is returned with the following components

ped Dataframe with trimmed subject removed

idTrimmed Vector of IDs of trimmed individuals

isTrimmed logical value indicating whether pedigree has been trimmed

bitSize Bit size of the trimmed pedigree

## See Also

```
pedigree.shrink
```

8 findUnavailable

findAvailNonInform

Find subjects from a pedigree who are available and uninformative

#### **Description**

Identify subjects to remove from a pedigree who are available but non-informative. This is the second step to remove subjects in pedigree.shrink if the pedigree does not meet the desired bit size.

## Usage

```
findAvailNonInform(ped, avail)
```

#### **Arguments**

ped A pedigree object

avail Vector of availability status (e.g. genotyped) 0/1 or TRUE/FALSE

#### Value

Vector of subject ids

#### See Also

```
pedigree.shrink
```

findUnavailable

Find unavailable subjects in a pedigree

## **Description**

Find the ID of subjects in a pedigree iteratively, as anyone who is not available and does not have an available descendant by successively removing unavailable terminal nodes. pedigree.trim carries out the remove of the subjects identified by findUnavailable.

#### Usage

```
findUnavailable(ped, avail)
pedigree.trim(removeID, ped)
```

## **Arguments**

ped A pedigree object with an id, findex, mindex, sex, plus other optional items

avail Vector of availability status (e.g., genotyped) 0/1 or TRUE/FALSE

removeID vector of subject ids of persons to trim from a pedigree

fixParents 9

## **Details**

Originally written as pedTrim by Steve Iturria, modified by Dan Schaid 2007. findUnavailable also calls excludeStrayMarryin to find stray available marry-ins who are isolated after trimming their unavailable offspring, and excludeUnavailFounders. If the subject ids are character, make sure none of the characters in the ids is a colon (":"), which is a special character used to concatenate and split subjects within the utility.

#### Value

findUnavailable returns a vector of subject ids for who can be removed. pedigree.trim returns a trimmed pedigree object.

#### **Side Effects**

relation matrix from pedigree.trim is trimmed of any special relations that include the subjects to trim

#### See Also

pedigree.shrink,

fixParents	Fix details on the parents for children of the pedigree	

## **Description**

Fix the sex of parents, add parents that are missing from the pedigree

## Usage

```
fixParents(id, dadid, momid, sex, missid = 0)
```

## Arguments

id	Identification variable for individual
dadid	Identification variable for father. Founders' parents should be coded to NA, or another value specified by missid.
momid	Identification variable for mother. Founders' parents should be coded to NA, or another value specified by missid.
sex	Gender of individual noted in 'id'. Either character ("male", "female", "unknown", "terminated") or numeric (1="male", 2="female", 3="unknown", 4="terminated") data is allowed. For character data the string may be truncated, and of arbitrary case.
missid	The founders are those with no father or mother in the pedigree. The dadid and momid values for these subjects will either be NA or the value of this variable. The default for missid is 0 if the id variable is numeric, and "" (the empty string) otherwise.

10 ibdMatrix

#### **Details**

First look to add parents whose ids are given in momid/dadid. Second, fix sex of parents. Last look to add second parent for children for whom only one parent id is given.

#### Value

A data.frame with id, dadid, momid, sex as columns

#### Author(s)

Jason Sinnwell

## **Examples**

ibdMatrix

Create an IBD matrix

#### **Description**

Transform identity by descent (IBD) matrix data from the form produced by external programs such as SOLAR into the compact form used by the coxme and lmekin routines.

## Usage

```
ibdMatrix(id1, id2, x, idmap, diagonal)
```

## Arguments

id1, id2	pairs of subject identifiers
x	the IBD value for that pair
idmap	an optional 2 column matrix or data frame whose first element is the internal value (as found in id1 and id2), and whose second element will be used for the dimnames of the result
diagonal	optional value for the diagonal element. If present, any missing diagonal elements in the input data will be set to this value.

kindepth 11

#### **Details**

The IBD matrix for a set of n subjects will be an n by n symmetric matrix whose i,j element is the contains, for some given genetic location, a 0/1 indicator of whether 0, 1/2 or 2/2 of the alleles for i and j are identical by descent. Fractional values occur if the IBD fraction must be imputed. The diagonal will be 1. Since a large fraction of the values will be zero, programs such as Solar return a data set containing only the non-zero elements. As well, Solar will have renumbered the subjects as 1:n in such a way that families are grouped together in the matrix; a separate index file contains the mapping between this new id and the original one. The final matrix should be labeled with the original identifiers.

#### Value

a sparse matrix of class dsCMatrix. This is the same form used for kinship matrices.

#### See Also

kinship, Matrix

kindepth Compute the depth of each subject in a pedigree

## **Description**

Mark each person as to their depth in a pedigree; 0 for a founder, otherwise depth =  $1 + \max(\text{father's depth}, \text{mother's depth})$ 

#### Usage

```
kindepth(id, dad.id, mom.id, align = FALSE)
```

## **Arguments**

id	Identification code for each individual
dad.id	Id code for the father
mom.id	Id code for the mother
align	If align=T, go one step further and try to make both parents of each child have the same depth. (This is not always possible). It helps the drawing program by lining up pedigrees that "join in the middle" via a marriage.

#### **Details**

In the case of an inbred pedigree a perfect alignment obeying extra=TRUE may not exist.

#### Value

an integer vector containing the depth for each subject

12 kinship

#### Author(s)

Terry Therneau

#### See Also

```
plot.pedigree
```

kinship Compute a kinship matrix

## Description

Compute the kinship matrix for a set of related autosomal subjects. The function is generic, and can accept a pedigree, pedigreeList, or vector as the first argument.

## Usage

```
kinship(id, ...)
## S3 method for class 'pedigree'
kinship(id, chrtype="autosome", ...)
## S3 method for class 'pedigreeList'
kinship(id, chrtype="autosome", ...)
## Default S3 method:
kinship(id, dadid, momid, sex, chrtype="autosome", ...)
```

## Arguments

id	either a pedigree object, pedigreeList object, or a vector of subject identifiers. Subject identifiers may be numeric or character.
dadid	for each subject, the identifier of the biological father. This is only used if id is a vector.
momid	for each subject, the identifier of the biological mother. This is only used if id is a vector.
sex	vector of sex values coded as 1=male, 2=female
chrtype	chromosome type. The currently supported types are "autosome" and "X" or "x".
	Any number of optional arguments

## **Details**

The function will usually be called with a pedigree or pedigreeList; the third form is provided for backwards compatability with an earlier release of the library that was less capable. The first argument is named id for the same reason. Note that when using the third form any information on twins is not available to the function.

makefamid 13

When called with a pedigreeList, i.e., with multiple families, the routine will create a block-diagonal-symmetric sparse matrix object of class dsCMatrix. Since the [i,j] value of the result is 0 for any two unrelated individuals i and j and a Matrix utilizes sparse representation, the resulting object is often orders of magnitude smaller than an ordinary matrix. When kinship is called with a single pedigree an ordinary matrix is returned.

Two genes G1 and G2 are identical by descent (IBD) if they are both physical copies of the same ancestral gene; two genes are identical by state if they represent the same allele. So the brown eye gene that I inherited from my mother is IBD with hers; the same gene in an unrelated individual is not

The kinship coefficient between two subjects is the probability that a randomly selected allele from a locus will be IBD between them. It is obviously 0 between unrelated individuals. For an autosomal site and no inbreeding it will be 0.5 for an individual with themselves, .25 between mother and child, .125 between an uncle and neice, etc.

The computation is based on a recursive algorithm described in Lange, which assumes that the founder alleles are all independent.

#### Value

a matrix of kinship coefficients.

#### References

K Lange, Mathematical and Statistical Methods for Genetic Analysis, Springer-Verlag, New York, 1997

#### See Also

pedigree, makekinship, makefamid

#### **Examples**

```
\label{eq:test1} $$\text{test1} < - \text{data.frame}(\text{id} = \text{c}(1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14),} \\ & \quad \text{mom} = \text{c}(0, 0, 0, 0, 2, 2, 4, 4, 6, 2, 0, 0, 12, 13),} \\ & \quad \text{dad} = \text{c}(0, 0, 0, 0, 1, 1, 3, 3, 3, 7, 0, 0, 11, 10),} \\ & \quad \text{sex} = \text{c}(0, 1, 0, 1, 0, 1, 0, 1, 0, 0, 0, 1, 1, 1)) \\ \text{tped} < - \text{with}(\text{test1}, \text{pedigree}(\text{id}, \text{dad}, \text{mom}, \text{sex})) \\ & \quad \text{round}(8*\text{kinship}(\text{tped})) \\ \end{aligned}
```

makefamid

Construct a family id from pedigree information

#### **Description**

Create a vector of length n, giving the family "tree" number of each subject. If the pedigree is totally connected, then everyone will end up in tree 1, otherwise the tree numbers represent the disconnected subfamilies. Singleton subjects give a zero for family number.

14 makekinship

#### Usage

```
makefamid(id, father.id, mother.id)
```

## Arguments

id Identifier for each subject in the set of pedigrees

father.id Identifier for the father. This will be 0 or "" for a founder.

mother.id Identifer for the mother.

#### **Details**

This command is depricated. The kinship command now can be applied directly to pedigreeList objects.

#### Value

An integer vector giving family groupings

#### Author(s)

Terry Therneau

#### See Also

makekinship

makekinship	Create a sparse kinship matrix	

## **Description**

Compute the overall kinship matrix for a collection of families, and store it efficiently.

#### Usage

```
makekinship(famid, id, father.id, mother.id, unrelated=0)
```

#### **Arguments**

famid a vector of family identif	ners
----------------------------------	------

id a vector of unique subject identifiers

father.id for each subject, the identifier of their biological father mother.id for each subject, the identifier of thier biological mother

unrelated subjects with this family id are considered to be unrelated singletons, i.e., not

related to each other or to anyone else.

minnbreast 15

#### **Details**

This command is depricated. The kinship command now can be applied directly to pedigreeList objects.

#### Value

a sparse kinship matrix of class bdsmatrix

#### See Also

kinship, makefamid

## **Examples**

```
# Data set from a large family study of breast cancer
# there are 26050 subjects in the file, from 426 families
## Not run:
> table(cdata$sex)
     F
 12699 13351
> length(unique(cdata$famid))
[1] 426
> kin1 <- makekinship(cdata$famid, cdata$gid, cdata$dadid, cdata$momid)</pre>
> dim(kin1)
[1] 26050 26050
> class(kin1)
[1] "bdsmatrix"
\# The next line shows that few of the elements of the full matrix are >0
> length(kin1@blocks)/ prod(dim(kin1))
[1] 0.00164925
# kinship matrix for the females only
> femid <- cdata$gid[cdata$sex=='F']</pre>
> femindex <- !is.na(match(dimnames(kin1)[[1]], femid))</pre>
> kin2 <- kin1[femindex, femindex]</pre>
# Note that "femindex <- match(femid, dimnames(kin1)[[1]])" is wrong, since
# then kin1[femindex, femindex] might improperly reorder the rows/cols
# (if families were not contiguous in cdata).
# However sort(match(femid, dimnames(kin1)[[1]])) would be okay.
## End(Not run)
```

minnbreast

Minnesota Breast Cancer Study

16 minnbreast

#### **Description**

Data from the Minnesota Breast Cancer Family Study. This contains extended pedigrees from 426 families, each identified by a single proband in 1945-52, with follow up for incident breast cancer.

#### Usage

data(minnbreast)

#### **Format**

minnbreast: A data frame with 28081 observations, one line per subject, on the following 14 variables.

id subject identifier

proband if 1, this subject is one of the original 426 probands

fatherid identifier of the father, if the father is part of the data set; zero otherwise

motherid identifier of the mother, if the mother is part of the data set; zero otherwise

family identifier

endage age at last follow-up or incident cancer

cancer 1= breast cancer (females) or prostate cancer (males), 0=censored

yob year of birth

education amount of education: 1-8 years, 9-12 years, high school graduate, vocational education beyond high school, some college but did not graduate, college graduate, post-graduate education, refused to answer on the questionairre

marstat marital status: married, living with someone in a marriage-like relationship, separated or divorced, widowed, never married, refused to answer the questionaiire

everpreg ever pregnant: never pregnant at the time of baseline survey, ever pregnant at the time of baseline survey

parity number of births

nbreast number of breast biopsies

sex M or F

bcpc part of one of the families in the breast/prostate cancer substudy: 0=no, 1=yes. Note that subjects who were recruited to the overall study after the date of the BP substudy are coded as zero.

#### Details

The original study was conducted by Dr. Elving Anderson at the Dight Institute for Human Genetics at the University of Minnesota. From 1944 to 1952, 544 sequential breast cancer cases seen at the University Hospital were enrolled, and information gathered on parents, siblings, offspring, aunts/uncles, and grandparents with the goal of understanding possible familial aspects of brest cancer. In 1991 the study was resurrected by Dr. Tom Sellers. Of the original 544 he excluded 58 prevalent cases, along with another 19 who had less than 2 living relatives at the time of Dr Anderson's survey. Of the remaining 462 families 10 had no living members, 23 could not be located and 8 refused, leaving 426 families on whom updated pedigrees were obtained. This gave a study with

pedigree 17

13351 males and 12699 females (5183 marry-ins). Primary questions were the relationship of early life exposures, breast density, and pharmacogenomics on incident breast cancer risk.

For a subset of the families data was gathered on prostate cancer risk for male subjects via questionairres sent to men over 40. Other than this, data items other than parentage are limited to the female subjects.

#### **Examples**

pedigree

Create pedigree structure

#### **Description**

Create pedigree structure in the format needed for plotting.

## Usage

```
pedigree(id, dadid, momid, sex, affected, status, relation, famid,
missid)
```

18 pedigree

#### **Arguments**

id Identification variable for individual dadid Identification variable for father. Founders' parents should be coded to NA, or another value specified by missid. Identification variable for mother. Founders' parents should be coded to NA, or momid another value specified by missid. Gender of individual noted in 'id'. Either character ("male", "female", "unknown", "terminated") sex or numeric (1="male", 2="female", 3="unknown", 4="terminated") data is allowed. For character data the string may be truncated, and of arbitrary case. affected A variable indicating affection status. A multi-column matrix can be used to give the status with respect to multiple traits. Logical, factor, and integer types are converted to 0/1 representing unaffected and affected, respectively. NAs are considered missing. Status (0="censored", 1="dead") status relation A matrix with 3 required columns (id1, id2, code) specifying special relationship between pairs of individuals. Codes: 1=Monozygotic twin, 2=Dizygotic twin, 3=Twin of unknown zygosity, 4=Spouse. (The last is necessary in order to place a marriage with no children into the plot.) If famid is given in the call to create pedigrees, then famid needs to be in the last column of the relation matrix. Note for tuples of  $\geq 3$  with a mixture of zygosities, the plotting is limited to showing pairwise zygosity of adjacent subjects, so it is only necessary to specify the pairwise zygosity, in the order the subjects are given or appear on the plot. famid An optional vector of family identifiers. If it is present the result will contain individual pedigrees for each family in the set, which can be extacted using subscripts. Individuals need to have a unique id within family. The founders are those with no father or mother in the pedigree. The dadid and missid

momid values for these subjects will either be NA or the value of this variable. The default for missid is 0 if the id variable is numeric, and "" (the empty

string) otherwise.

#### Value

An object of class pedigree or pedigreeList Containing the following items: famid id findex mindex sex affected status relation

## See Also

```
plot.pedigree, autohint
```

#### **Examples**

```
data(minnbreast)
bpeds <- with(minnbreast,</pre>
    pedigree(id, fatherid, motherid, sex, affected=proband, famid=famid))
## pedigree with id=8
```

pedigree.legend 19

```
bped.id8 <- bpeds['8']</pre>
print(bped.id8)
## to plot:
#plot(bped.id8)
## show this pedigree with mixed zygosity quadruplets
rel8 <- data.frame(id1=c(137,138,139), id2=c(138,139,140), code=c(1,2,2))
bped.id8 <- with(minnbreast[minnbreast$famid==8,],</pre>
     pedigree(id, fatherid, motherid, sex, affected=proband,
relation=rel8))
## to plot:
#plot(bped.id8)
## the 8th pedigree
bped8 <- bpeds[8]</pre>
print(bped8)
## to plot:
#plot(bped8, cex=.5)
```

pedigree.legend

Plot a pedigree legend

#### **Description**

Plot a pedigree legend that describes the affected indiactors for a subject

## Usage

```
pedigree.legend(ped, labels = dimnames(ped$affected)[[2]], edges = 200, radius=NULL, location="bottomright", new=TRUE, density = c(-1, 35, 65, 20), angle = c(90, 65, 40, 0), ...)
```

#### **Arguments**

ped	A pedigree object with id, dadid, momid, sex, affected
labels	names for the affected indicators
edges	Number of edges for each polygon. Higher numbers give better resolution for the circle.
radius	length of the circle's radius
location	Similar to how the location of a regular legend is given, used only if new=TRUE. A character string indicating which of the four corners to plot the legend, given by "bottomright", "bottomleft", "topleft", or "topright".
new	Logical. If TRUE, plot the legend on the current plot. Otherwise, plot on a separate plot.

20 pedigree.shrink

density	Density of lines shaded in sections of the circle. These match the density settings for the plot.pedigree function.
angle	Angle at which lines are shaded in sections of the circle. These match the angles for the plot.pedigree function.
	optional parameters for the plot function that apply to text.

#### **Details**

Adapt the pie() function to plot a circle with affected indicators. When new=TRUE, much care is needed to keep track of location and scaling of lines and text.

#### Value

Nothing is returned.

#### See Also

```
plot.pedigree
```

## **Examples**

pedigree.shrink Trim a pedigree to specified bit size with priority placed on trimming uninformative subjects.

## Description

Iteratively remove subjects from the pedigree. First remove uninformative subjects, i.e., unavailable (not genotyped) with no available descendants. Next, available terminal subjects with unknown phenotype if both parents available. Last, iteratively shrinks pedigrees by preferentially removing: 1. Subjects with unknown affected status 2. Subjects with unaffected affected status 3. Affected subjects.

pedigree.shrink 21

## Usage

```
pedigree.shrink(ped, avail, affected=NULL, seed=NULL, maxBits=16)
```

## Arguments

ped	A pedigree object with id, dadid, momid, sex, affected
avail	Vector of availability status (genotyped) 0/1 or TRUE/FALSE
affected	Vector of affected status, 0/1 or TRUE/FALSE. If not given, use the first column of the affected matrix of the pedigree object.
seed	An integer or a saved copy of .Random.seed. This allows simulations to be reproduced by using the same initial seed.
maxBits	Target bit size. Pedigree will be trimmed until bit size is <= maxBits.

#### **Details**

If the subject ids are character, make sure none of the characters in the ids is a colon (":"), which is a special character used to concatenate and split subjects within the findUnavailable utility within the pedigree.shrink function.

#### Value

ped0bj

An object of class pedigree.shrink which is a list with the following components:

pedigree object for the trimmed pedigree

idTrimmed	Vector of IDs of trimmed individuals
idList	List of IDs trimmed each of three stages: unavail, noninform, affect
bitSize	Bit size of the pedigree at each stage of trimming
avail	vector of availability for members of the trimmed pedigree
pedSizeOriginal	
	The number of individuals in the input pedigree
pedSizeIntermed	
	The number of individuals in the pedigree after removing unavailable subjects and before beginning the itertive shrinking.
pedSizeFinal	The number of individuals in the final pedigree
seed	The random seed used

22 pedigree.unrelated

#### **Examples**

pedigree.unrelated

Determine set of maximum number of unrelated available subjects from a pedigree

## **Description**

Determine set of maximum number of unrelated available subjects from a pedigree, given vectors id, father, and mother for a pedigree structure, and status vector of T/F for whether each subject is available (e.g. has DNA)

## Usage

```
pedigree.unrelated(ped, avail)
```

## Arguments

ped A pedigree objects with unique id, father index, mother index avail Vector of availability status (e.g., genotyped) 0/1 or TRUE/FALSE

pedigree.unrelated 23

#### **Details**

This is a greedy algorithm that uses the kinship matrix, sequentially removing rows/cols that are non-zero for subjects that have the most number of zero kinship coefficients (greedy by choosing a row of kinship matrix that has the most number of zeros, and then remove any cols and their corresponding rows that are non-zero. To account for ties of the count of zeros for rows, a random choice is made. Hence, running this function multiple times can return different sets of unrelated subjects.

#### Value

A vector of the ids of subjects that are unrelated.

#### See Also

plot.pedigree

plot pedigrees

#### **Description**

plot objects created with the pedigree function

## Usage

#### **Arguments**

width

ment of pedigrees.

X	object created by the function pedigree.
id	id variable - used for labeling.
status	can be missing. If it exists, 0=alive/missing and 1=death.
affected	vector, or matrix with up to 4 columns for affected indicators. Subject's symbol is divided into sections for each status, shaded if indicator is 1, not-shaded for 0, and symbol "?" if missing (NA)
affected.label	vector of text labels to describe affection statuses
cex	controls text size. Default=1.
col	color for each id. Default assigns the same color to everyone.
col.label	vector of text labels associated with each color in the legend.
symbolsize	controls symbolsize. Default=1.
branch	defines how much angle is used to connect various levels of nuclear families.
packed	default=T. If T, uniform distance between all individuals at a given level.
align	these parameters control the extra effort spent trying to align children underneath

parents, but without making the pedigree too wide. Set to F to speed up plotting. default=8. For a packed pedigree, the minimum width allowed in the realign-

plot.pedigree 25

defines density used in the symbols. Takes up to 4 different values.

mar margin parmeters, as in the par function

angle defines angle used in the symbols. Takes up to 4 different values.

keep.par Default = F, allows user to keep the parameter settings the same as they were for

plotting (useful for adding extras to the plot)

subregion 4-element vector for (min x, max x, min depth, max depth), used to edit away

portions of the plot coordinates returned by align.pedigree

pconnect when connecting parent to children the program will try to make the connecting

line as close to vertical as possible, subject to it lying inside the endpoints of the line that connects the children by at least pconnect people. Setting this option to a large number will force the line to connect at the midpoint of the children.

... Extra options that feed into the plot function

#### **Details**

Two important parameters control the looks of the result. One is the user specified maximum width. The smallest possible width is the maximum number of subjects on a line, if the user's suggestion is too low it is increased to 1+ that amount (to give just a little wiggle room). To make a pedigree where all children are centered under parents simply make the width large enough, however, the symbols may get very small.

The second is align, a vector of 2 alignment parameters a and b. For each set of siblings at a set of locations x and with parents at p=c(p1,p2) the alignment penalty is

$$(1/k^a)\sum i = 1k[(x_i - (p1 + p2)/2)]^2$$

sum(x- mean(p))^2/(k^a) where k is the number of siblings in the set. when \$a=1\$ moving a sibship with \$k\$ sibs one unit to the left or right of optimal will incur the same cost as moving one with only 1 or two sibs out of place. If \$a=0\$ then large sibships are harder to move than small ones, with the default value \$a=1.5\$ they are slightly easier to move than small ones. The rationale for the default is as long as the parents are somewhere between the first and last siblings the result looks fairly good, so we are more flexible with the spacing of a large family. By tethering all the sibs to a single spot they are kept close to each other. The alignment penalty for spouses is  $b(x_1 - x_2)^2$ , which tends to keep them together. The size of \$b\$ controls the relative importance of sib-parent and spouse-spouse closeness.

## Value

an invisible list containing

plist a list that contains all the position information for plotting the pedigree. This

will useful for further functions (yet unwritten) for manipulating the plot, but

likely not to an ordinary user.

x,y the x an and y plot coordinates of each subject in the plot. The coordinate is

for the top of the plotted symbol. These will be in the same order as the input pedigree. If someone in the pedigree does not appear in the plot their coordinates will be NA. If they appear multiple times one of the instances is chosen. (Which

one is a function of the order in which the pedigree was constructed.)

26 plot.pedigree.shrink

boxh	the height of the symbol, in user coordinates
boxw	the width of the symbol

call a copy of the call that generated the plot

#### **Side Effects**

creates plot on current plotting device.

#### See Also

```
pedigree
```

## **Examples**

 $\verb|plot.pedigree.shrink|| plot pedigree.shrink|| object|| that is a \textit{shrunk pedigree object}||$ 

## Description

Plot the pedigree object that is the trimmed pedigree.shrink object along with colors based on availability and affection status.

## Usage

```
## S3 method for class 'pedigree.shrink'
plot(x, bigped=FALSE, title="", xlegend="topright", ...)
```

printBanner 27

#### **Arguments**

х	A pedigree.shrink object, which contains a pedigree object and information about which subject was removed.
bigped	Logical value indicating whether pedigree should be compacted to fit in plotting region. If T, then packed=F is used in pedigree() along with smaller symbol sizes.
title	Optional plot title
xlegend	The x argument for the legend command, which allows coordinates or, more conveniently, options such as "topright", "right", "left", "bottomleft", etc., which is useful for pedigrees that cover most of the plot region.
	Optional arguments to plot method

```

## **Examples**

printBanner

Print a nice banner

## Description

Print a nice banner with a border above and below the text. It centers the text, and adjusts to the width system option by breaking into multiple lines when needed.

## Usage

```
printBanner(str, banner.width=options()$width, char.perline=.75*banner.width, border="=")
```

28 sample.ped

#### **Arguments**

str character string - a title within the banner

banner.width width of banner, the default is set to fit current options

char.perline number of characters per line for the title, the default is 75% of the banner.width

parameter

border type of character for the border

#### **Details**

This function prints a nice banner in both R and S-PLUS

#### Value

nothing is returned

## **Examples**

sample.ped

Two example pedigrees

## **Description**

Two pedigrees of different size for testing pedigree operations

## Usage

```
data(sample.ped)
```

## **Format**

A data frame with 55 observations on the following 7 variables.

```
ped pedigree id
id subject id, unique to each ped
father id of the subject's father
```

testped1 29

```
mother id of the subject's mother
sex 1=male, 2=female, 3=unknown
affected affection status; 0=unaffected, 1=affected, NA=unknown
avail is DNA data available; 0=unavailable, 1=available
```

## **Examples**

```
data(sample.ped)
```

testped1

testped1

## Description

Sample pedigree

## Usage

```
data(testped1)
```

#### **Format**

A data frame with 79 subjects in one family with the following variables.

```
id subject id, unique to each ped
father id of the subject's father
mother id of the subject's mother
sex 1=male, 2=female
```

## Examples

```
data(testped1)
testped1[1:20,]
