Package 'mi'

June 6, 2022

Type Package
Title Missing Data Imputation and Model Checking
Version 1.1
Date 2022-06-05

Description

The mi package provides functions for data manipulation, imputing missing values in an approximate Bayesian framework, diagnostics of the models used to generate the imputations, confidence-building mechanisms to validate some of the assumptions of the imputation algorithm, and functions to analyze multiply imputed data sets with the appropriate degree of sampling uncertainty.

Description

The mi package performs multiple imputation for data with missing values. The algorithm iteratively draws imputed values from the conditional distribution for each variable given the observed and imputed values of the other variables in the data. The process approximates a Bayesian framework; multiple chains are run and convergence is assessed after a pre-specified number of iterations within each chain. The package allows customization of the conditional model and the treatment of missing values for each variable. In addition, the package provides graphics to visualize missing data patterns, to diagnose the models used to generate the imputations, and to assess convergence. Functions are included to run statistical models post-imputation with the appropriate degree of sampling uncertainty.

01missing_variable

Class "missing_variable" and Inherited Classes

Description

The missing_variable class is essentially the data comprising a variable plus all the metadata needed to understand how its missing values will be imputed. However, no variable is merely of missing_variable class; rather every variable is of a class that inherits from the missing_variable class. Even if a variable has no missing values, it needs to be coerced to a class that inherits from the missing_variable class before it can be used to impute values of other missing_variables. Understanding the properties of different subclasses of the missing_variable class is essential for modeling and imputing them. The missing_data.frame-class is essentially a list of objects that inherit from the missing_variable class, plus metadata need to understand how these missing_variables relate to each other. Most users will never need to call missing_variable directly since it is called by missing_data.frame.

Usage

```
missing_variable(y, type, ...)
## Hidden arugments not included in the signature:
## favor_ordered = TRUE, favor_positive = FALSE,
## variable_name = deparse(substitute(y))
```

4 01missing_variable

Arguments

У

Can be any vector, some of whose values may be NA, which will comprise the **raw_data** slot of a missing_variable (see the Slots section). It is recommended that this vector *not* have any transformations, such as a log-transformation. Any continuous variable can be transformed using the function in its **transformation** slot. The transformations and other discretionary aspects of a missing_variable are typically changed by calling the change function on a missing_data.frame See the Slots section for more details.

type

Missing or a character string among the classes that inherit from the missing_variable class. If missing, the constructor will guess (sometimes incorrectly) based on the characteristics of the variable. The best way to improve the guessing of categorical variables is to use the factor function — possibly with ordered = TRUE — to create (possibly ordered) factors that will correctly be coerced to objects of unordered-categorical-class and ordered-categorical-class respectively. If you fail to do so, the hidden arguments that are not included in the signature affect the guesses. If favor_ordered = TRUE, which is the default, it will tend to guess that variables with few unique values are should be coerced to ordered-categorical-class and unordered-categorical-class otherwise. If favor_positive = FALSE, which is the default, it will tend to guess that variables with many unique values are merely continuous, whether or not all the observed values are positive. If favor_positive = TRUE nonnegative or positive variables will get coerced to nonnegative-continuous-class or positive-continuous-class. See the Slots section and the specific help pages for more details on the subclasses.

. .

Further hidden arguments that are not in the signature. The favor_ordered and favor_positive arguments are documented immediately above. The variable name argument can be used to control what gets put in the **variable_name** slot, see the Slots section below.

Value

The missing_variable function returns an object that inherits from the missing_variable class.

Objects from the Classes

The missing_variable class is virtual, so no objects may be created from it. However, the missing_variable generic function can be used to instantiate an object that inherits from the missing_variable class by specifying its type argument. A user would call the missing_data.frame function on a data.frame, which in turn calls the missing_variable function on each column of the data.frame using various heuristics to guess the type argument.

Slots

In the following table, indentation indicates inheritance from the class with less indentation, and italics indicates that the class is virtual so no variables can be created with that class. Inherited classes inherit the transformations, families, link functions, and fit_model-methods from their parent class, although these are often superceeded by analogues that are tailored for the inherited

01missing_variable 5

class. Also note, the default transformation for the continuous class is a standardization using *twice* the standard deviation of the observed values.

The distinction between the transformation entailed by the family and the transformation entailed by the function in the **tranformation** slot may be confusing at this point. The former pertains to how the linear predictor of a variable is mapped to the space of a variable when it is on the left-hand side of a generalized linear model. The latter pertains — for continuous variables only — to how the values in the **raw_data** slot are mapped into those in the **data** and thus affects how a continuous variable enters into the model whether it is on the left or right-hand side. The classes are discussed in much more detail below.

Class name [transformation]	Default family and link	Default fit_model
missing_variable	none	throws error
categorical	none	throws error
unordered-categorical	<pre>binomial(link = 'logit')</pre>	multinom
ordered-categorical	<pre>binomial(link = 'logit')</pre>	bayespolr
binary	<pre>binomial(link = 'logit')</pre>	bayesglm
interval	<pre>gaussian{link = 'identity'}</pre>	survreg
continuous[standardize]	<pre>gaussian{link = 'identity'}</pre>	bayesglm
semi-continuous[identity]		
nonnegative-continuous[logshift]		
SC_proportion[squeeze]	<pre>binomial(link = 'logit')</pre>	betareg
positive-continuous[log]		
proportion[identity]	<pre>binomial(link = 'logit')</pre>	betareg
bounded-continuous[identity]		
count	<pre>quasipoisson{link = 'log'}</pre>	bayesglm
irrelevant		throws error
fixed		throws error

The missing_variable class is virtual and has the following slots (this information is primarily directed at developeRs):

variable_name: Object of class character of length one naming the variable

raw_data: Object of class "ANY" representing the observations on a variable, some of which may be NA. No method should ever change this slot at all. Instead, methods should change the **data** slot.

data: Object of class "ANY", which is initially a copy of the **raw_data** slot — transformed by the function in the **transformation** slot for continuous variables only — and whose NA values are replaced during the multiple imputation process. See mi

n_total: Object of class "integer" which is the length of the data slot

all_obs: Object of class "logical" of length one indicating whether all values of the **data** slot are observed and thus not NA

n_obs: Object of class "integer" of length one indicating the number of values of the **data** slot that are observed and thus not NA

which_obs: Object of class "integer", which is a vector indicating the positions of the observed values in the **data** slot

6 01missing_variable

all_miss: Object of class "logical" of length one indicating whether all values of the **data** slot are NA

- n_miss: Object of class "integer" of length one indicating the number of values of the **data** slot that are NA
- which_miss: Object of class "integer", which is a vector indicating the positions of the missing values in the **data** slot
- n_extra: Object of class "integer" of length one indicating how many (missing) observations have been added to the end of the data slot that are not included in the raw_data slot. Although the extra values will be imputed, they are not considered to be "missing" for the purposes of defining the previous three slots
- which_extra: Object of class "integer", which is a vector indicating the positions of the extra values at the end of the **data** slot
- n_unpossible: Object of class "integer" of length one indicating the number of values that are logically or structurally unobservable
- which_unpossible: Object of class "integer" indicating the positions of the unpossible values in the **data** slot
- n_drawn: Object of class "integer" of length one which is the sum of the n_miss and n_extra
 slots
- which_drawn: Object of class "integer" which is a vector concatinating the **which_miss** and **which extra** slots
- imputation_method: Object of class "character" of length one indicating how the NA values are to be imputed. Possibilities include "ppd" for imputation from the posterior predictive distribution, "pmm" for imputation via predictive mean matching, "mean" for meanimputation, "median" for median-imputation, "expectation" for conditional mean-imputation. With enough programming effort, other kinds of imputation can be defined and specified here.
- family: Object of class "WeAreFamily" that will typically be passed to glm and similar functions during the multiple imputation process
- known_families: Object of class character indicating the families that are known to be supported for a class; see family
- known_links: Object of class character indicating what link functions are known to be supported by the elements of the **known_families** slot; see family
- imputations: Object of class "MatrixTypeThing" with rows equal to the number of iterations (initially zero) of the multiple imputation algorithm and columns equal to the **n_drawn** slot. The rows are appropriately extended and then filled by the **mi** function
- done: Object of class "logical" of length one indicating whether the NA values in the **data** slot have been replaced by imputed values
- parameters: Object of class "MatrixTypeThing" with rows equal to the number of iterations (initially zero) of the multiple imputation algorithm and columns equal to the number of estimated parameters when modeling the **data** slot. The rows are appropriately extended and then filled by the mi function
- model: Object of class "ANY" which can be filled by an object that is output by one of the fit_model-methods, which is done by default by mi when all the iterations have completed

fitted: Object of class "ANY" although typically a vector or matrix that contains the fitted values of the model in the slot immediately above. Note that the **fitted** slot is filled by default by mi, although the **model** slot is left empty by default to save RAM.

estimator: Object of class "character" of length one indicating which pre-existing fit_model to use for an unordered-categorical variable. Options are "mnl", in which multinom from the **nnet** package is used to fit the values of the unordered categorical variable; and "rnl", in which each category is separately modeled as the positive binary outcome against all other categories using a bayesglm fit_model and the probabilities of each category are normalized to sum to 1 after each model is run. In general, "rnl" is slightly less accurate than "mnl", but runs much more quickly especially when the unordered categorical variable has many unique categories.

The WeAreFamily class is a class union of character and family, while the MatrixTypeThing class is a class union of matrix only at the moment.

mdf <- missing_data.frame(nlsyV) # this calls missing_variable() internally
show(mdf)</pre>
```

02missing_data.frame Class "missing_data.frame"

Description

This class is similar to a data.frame but is customized for the situation in which variables with missing data are being modeled for multiple imputation. This class primarily consists of a list of missing_variables plus slots containing metadata indicating how the missing_variables relate to each other. Most operations that work for a data.frame also work for a missing_data.frame.

Usage

```
missing_data.frame(y, ...)
## Hidden arguments not included in the signature
## favor_ordered = TRUE, favor_positive = FALSE,
## subclass = NA_character_,
## include_missingness = TRUE, skip_correlation_check = FALSE
```

Arguments

y Usually a data. frame, possibly a numeric matrix, possibly a list of missing_variables.

.. Hidden arguments. The favor_ordered and favor_positive arguments are passed to the missing_variable function and are documented under the type argument. Briefly, they affect the heuristics that are used to guess what class a variable should be coerced to. The subclass argument defaults to NA and can be used to specify that the resulting object should inherit from the miss-

Any further arguments are passed to the initialize-methods for a missing_data.frame. They currently are include_missingness, which defaults to TRUE and indicates that the missingness pattern of the other variables should be included when modeling a particular missing_variable, and skip_correlation_check, which defaults to FALSE and indicates whether to skip the default check for whether the observed values of each pair of missing_variables has a perfect absolute Spearman correlation.

ing data.frame class rather than be an object of missing_data.frame class.

Details

In most cases, the first step of an analysis is for a useR to call the missing_data.frame function on a data.frame whose variables have some NA values, which will call the missing_variable function on each column of the data.frame and return the list that fills the variable slot. The classes of the list elements will depend on the nature of the column of the data.frame and various fallible heuristics. The success rate can be enhanced by making sure that columns of the original data.frame that are intended to be categorical variables are (ordered if appropriate) factors with labels. Even in the best case scenario, it will often be necessary to utlize the change function to modify various discretionary aspects of the missing_variables in the variables slot of the missing_data.frame. The show method for a missing_data.frame should be utilized to get a quick overview of the missing_variables in a missing_data.frame and recognized what needs to be changed.

Value

The missing_data.frame constructor function returns an object of class missing_data.frame or that inherits from the missing_data.frame class.

Objects from the Class

Objects can be created by calls of the form new("missing_data.frame", ...). However, useRs almost always will pass a data.frame to the missing_data.frame constructor function to produce an object of missing_data.frame class.

Slots

This section is primarily aimed at developeRs. A missing_data.frame inherits from data.frame but has the following additional slots:

- variables: Object of class "list" and each list element is an object that inherits from the missing_variable-class
- no_missing: Object of class "logical", which is a vector whose length is the same as the length of the **variables** slot indicating whether the corresponding missing_variable is fully observed
- patterns: Object of class factor whose length is equal to the number of observation and whose elements indicate the missingness pattern for that observation
- DIM: Object of class "integer" of length two indicating first the number of observations and second the length of the **variables** slot
- DIMNAMES: Object of class "list" of length two providing the appropriate number rownames and column names
- postprocess: Object of class "function" used to create additional variables from existing variables, such as interactions between two missing_variables once their missing values have been imputed. Does not work at the moment
- index: Object of class "list" whose length is equal to the number of missing_variables with some missing values. Each list element is an integer vector indicating which columns of the X slot must be dropped when modeling the corresponding missing_variable
- X: Object of MatrixTypeThing-class with rows equal to the number of observations and is loosely related to a model.matrix. Rather than repeatedly parsing a formula during the multiple imputation process, this X matrix is created once and some of its columns are dropped when modeling a missing_variable utilizing the index slot. The columns of the X matrix consists of numeric representations of the missing_variables plus (by default) the unique missingness patterns
- weights: Object of class "list" whose length is equal to one or the number of missing_variables with some missing values. Each list element is passed to the corresponding argument of bayesglm and similar functions. In particular, some observations can be given a weight of zero, which should drop them when modeling some missing_variables
- priors: Object of class "list" whose length is equal to the number of missing_variables and whose elements give appropriate values for the priors used by the model fitting function wraped by the fit_model-methods; see, e.g., bayesglm
- correlations: Object of class "matrix" with rows and columns equal to the length of the variables slot. Its strict upper triangle contains Spearman correlations between pairs of variables (ignoring missing values), and its strict lower triangle contains Squared Multiple Correlations (SMCs) between a variable and all other variables (ignoring missing values). If either a Spearman correlation or a SMC is very close to unity, there may be difficulty or error messages during the multiple imputation process.
- done: Object of class "logical" of length one indicating whether the missing values have been imputed
- workpath: Object of class character of length one indicating the path to a working directory that is used to store some objects

Methods

There are many methods that are defined for a missing_data.frame, although some are primarily intended for developers. The most relevant ones for users are:

- change signature(data = "missing_data.frame", y = "ANY", what = "character", to = "ANY")
 which is used to change discretionary aspects of the missing_variables in the variables slot
 of a missing_data.frame
- **hist** signature(x = "missing_data.frame") which shows histograms of the observed variables that have missingness
- image signature(x = "missing_data.frame") which plots an image of the missingness slot to visualize the pattern of missingness when grayscale = FALSE or the pattern of missingness in light of the observed values (grayscale = TRUE, the default)
- mi signature(y = "missing_data.frame", model = "missing") which multiply imputes the missing values
- **show** signature(object = "missing_data.frame") which gives an overview of the salient characteristics of the missing_variables in the **variables** slot of a missing_data.frame
- summary signature(object = "missing_data.frame") which produces the same result as the
 summary method for a data.frame

There are also S3 methods for the dim, dimnames, and names generics, which allow functions like nrow, ncol, rownames, colnames, etc. to work as expected on missing_data.frames. Also, accessing and changing elements for a missing_data.frame mostly works the same way as for a data.frame

show(mdfs)</pre>
```

03change

Make Changes to Discretionary Characteristics of Missing Variables

Description

These methods change the family, imputation method, size, type, and so forth of a missing_variable. They are typically called immediately before calling mi because they affect how the conditional expectation of each missing_variable is modeled.

Usage

```
change(data, y, to, what, ...)
change_family(data, y, to, ...)
change_imputation_method(data, y, to, ...)
change_link(data, y, to, ...)
change_model(data, y, to, ...)
change_size(data, y, to, ...)
change_transformation(data, y, to, ...)
change_type(data, y, to, ...)
```

Arguments

У

what

data A missing_data.frame (typically) but can be missing for all but the change function

Tunction

A character vector (typically) naming one or more missing_variables within the missing_data.frame specified by the **data** argument. Alternatively, **y** can be the name of a class that inherits from missing_variable, in which case all missing_variables of that class within data will be changed. Can also be an vector of integers or a logical vector indicating which missing_variables to

change.

Typically a character string naming what is to be changed, such as "family", "imputation_method", "size", "transformation", "type", "link", or "model". Alternatively, it can be a scalar value, in which case all occurances of that value

for the variable indicated by y will be changed to the value indicated by to

12 03change

Typically a character string naming what y should be changed to, such as one of the admissible families, imputation methods, transformations, or types. If missing, then possible choices for the to argument will be helpfully printed on the screen. If what is a number, then to should be the number (or NA) that the value designated by what will be recoded to. See the Details section for more information.

... Other arguments, not currently utilized

Details

In order to run mi correctly, data must first be specified to be ready for multiple imputation using the missing_data.frame function. For each variable, missing_data.frame will record information required by mi: the variable's type, distribution family, and link function; whether a variable should be standardized or tranformed by a log function or square root; what specific model to use for the conditional distribution of the variable in the mi algorithm and how to draw imputed values from this model; and whether additional rows (for the purposes of prediction) are required. missing_data.frame will attempt to guess the correct type, family, and link for each variable based on its class in a regular data.frame. These guesses can be checked with show and adjusted if necessary with change. Any further additions to the model in regards to variable transformations, custom conditional models, or extra non-observed predictive cases must be specified with change before mi is run.

In general, most users will only use the change command. change will then call change_family, change_imputation_method, change_link, change_model, change_size, change_transformation, or change_type depending on what characteristic is specified with the what option. The other change_* functions can be called directly but are primarily intended to be called indirectly by the change function.

- what = "type" Change the subclass of variable(s) y. to should be a character vector whose elements are subclasses of the missing_variable-class and are documented further there.
 Among the most commonly used subclasses are "unordered-categorical", "ordered-categorical",
 "binary", "interval", "continuous", "count", and "irrelevant".
- what = "family" Change the distribution family for variable(s) y. to must be of class family or a list where each element is of class family. If a variable is of binary-class, then the family must be binomial (the default) or possibly quasibinomial. If a variable is of ordered-categorical-class or unordered-categorical-class, use the multinomial family. If a variable is of count-class, then the family must be quasipoisson (the default) or poisson. If a variable is continuous, there are more choices for its family, but gaussian is the default and the others are not supported yet.
- what = "link" Change the link function for variable(s) y. to can be any of the supported link functions for the existing **family**. See family for details; however, not all of these link functions have appropriate fit_model and mi-methods yet.
- what = "model" Change the conditional model for variable y. It usually is not necessary to change the model, since it is actually determined by the class, family, and link function of the variable. This option can be used, however, to employ models that are not among those listed above.to should be a character vector of length one indicating what model should be used during the imputation process. Valid choices for binary variables include "logit", "probit" "cauchit", "cloglog", or quasilikelihoods "qlogit", "qprobit", "qcauchit", "qcloglog". For ordinal variables, valid choices include "ologit", "oprobit", "ocauchit", and "ocloglog".

03change 13

For count variables, valid choices include "qpoisson" and "poisson". Currently the only valid option for gaussian variables is "linear". To change the model for unordered-categorical variables, see the estimator slot in missing_variable.

what = "imputation_method" Change the method for drawing imputed values from the conditional model specified for variable(s) y. to should be a character vector of length one or of the same length as y naming one of the following imputation methods: "ppd" (posterior predictive distribution), "pmm" (predictive mean matching), "mean" (mean imputation), "median" (median imputation), "expectation" (conditional expectation imputation).

what = "size" Optionally add additional rows for the purposes of prediction. to should be a single integer. If to is non-negative but less than the number of rows in the missing_data.frame given by the data argument, then missing_data.frame is augmented with to more rows, where all the additional observations are missing. If to is greater than the number of rows in the missing_data.framegiven by the data argument, then the missing_data.frame is extended to have to rows, where the observations in the surplus rows are missing. If to is negative, then any additional rows in the missing_data.frame given by the data argument are removed to restore it to its original size.

what = "transformation" Specify a particular transformation to be applied to variable(s) y. to should be a character vector of length one or of the same length as y indicating what transformation function to use. Valid choices are "identity" for no transformation, "standardize" for standardization (using twice the standard deviation of the observed values), "log" for natural logarithm transformation, "logshift" for a log(y + a) transformation where a is a small constant, or "sqrt" for square-root transformation. Changing the transformation will also change the inverse transformation in the appropriate way. Any other value of to will produce an informative error message indicating that the transformation and inverse transformation need to be changed manually.

what = a value Finally, if both what and to are values then the former is recoded to the latter for all occurances within the missing variable indicated by y.

Value

If the **data** argument is not missing, then the method returns this argument with the specified changes. If **data** is missing, then the method returns an object that inherits from the missing_variable-class with the specified changes.

04mi

Multiple Imputation

Description

The mi function cannot be run in isolation. It is the most important step of a multi-step process to perform multiple imputation. The data must be specified as a missing_data.frame before mi is used to impute missing values for one or more missing_variables. An iterative algorithm is used where each missing_variable is modeled (using fit_model) as a function of all the other missing_variables and their missingness patterns. This documentation outlines the technical uses of the mi function. For a more general discussion of how to use mi for multiple imputation, see mi-package.

Usage

```
mi(y, model, ...)
## Hidden arguments:
## n.iter = 30, n.chains = 4, max.minutes = Inf, seed = NA, verbose = TRUE,
## save_models = FALSE, parallel = .Platform$OS.type != "windows"
```

Arguments

model

y Typically an object that inherits from the missing_data.frame-class, although many methods are defined for subclasses of the missing_variable-class. Alternatively, y = "parallel" the appropriate parallel backend will be registered but no imputation performed. See the Details section.

Missing when y = "parallel" or when y inherits from the missing_data.frame-class but otherwise should be the result of a call to fit_model.

Further arguments, the most important of which are

n.iter number of iterations to perform, defaulting to 30

n.chains number of chains to use, ideally equal to the number of virtual cores available for use, and defaulting to 4

max.minutes hard time limit that defaults to 20

seed either NA, which is the default, or a psuedo-random number seed

- verbose logical scalar that is TRUE by default, indicating that progress of the iterative algorithm should be printed to the screen, which does not work under Windows when the chains are executed in parallel
- save_models logical scalar that defaults to FALSE but if TRUE indicates that the models estimated on a frozen completed dataset should be saved. This option should be used if the user is interested in evaluating the quality of the models run after the last iteration of the mi algorithm, but saving these models consumes much more RAM
- debug logical scalar indicating whether to run in debug mode, which forces the processing to be sequential, and allows developers to capture errors within chains
- parallel if TRUE, then parallel processing is used, if available. If FALSE, sequential processing is used. In addition, the argument may be an object produced by makeCluster

Details

It is important to distinguish the two mi methods that are most relevant to users from the many mi methods that are less relevant. The primary mi method is that where y inherits from the missing_data.frame-class and model is omitted. This method "does" the imputation according to the additional arguments described under ... above and returns an object of class "mi". Executing two or more independent chains is important for monitoring the convergence of each chain, see Rhats.

If the chains have not converged in the amount of iterations or time specified, the second important mi method is that where y is an object of class "mi" and model is omitted, which continues a previous run of the iterative imputation algorithm. All the arguments described under ... above remain applicable, except for n. chains and save_RAM because these are established by the previous run that is being continued.

The numerous remaining methods are of less importance to users. One mi method is called when y = "parallel" and model is omitted. This method merely sets up the parallel backend so that the chains can be executed in parallel on the local machine. We use the mclapply function in the parallel package to implement parallel processing on non-Windows machines, and we use the snow package to implement parallel processing on Windows machines; we refer users to the documentation for these packages for more detail about parallel processing. Parallel processing is used by default on machines with multiple processors, but sequential processing can be used instead by using the parallel=FALSE option. If the user is not using a mulitcore computer, sequential processing is used instead of parallel processing.

The first two mi methods described above in turn call a mi method where y inherits from the missing_data.frame-class and model is that which is returned by one of the fit_model-methods. The methods impute values for the originally missing values of a missing_variable given a fitted model, according to the imputation_method slot of the missing_variable in question. Advanced users could define new subclasses of the missing_variable-class in which case it may be necessary to write such a mi method for the new class. It will almost certainly be necessary to add to the fit_model-methods. The existing mi and fit-model-methods should provide a template for doing so.

16 04mi

Value

If model is missing and n. chains is positive, then the mi method will return an object of class "mi", which has the following slots:

call the call to mi

data a list of missing_data. frames, one for each chain

total_iters an integer vector that records how many iterations have been performed

There are a few methods for such an object, such as show, summary, dimnames, nrow, ncol, etc.

If mi is called on a missing_data.frame with model missing and a nonpositive n.chains, then the missing_data.frame will be returned after allocating storeage.

If model is not missing, then the mi method will impute missing values for the y argument and return it.

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

Convergence Diagnostics

Description

These functions are used to gauge whether mi has converged.

Usage

```
Rhats(imputations, statistic = c("moments", "imputations", "parameters"))
mi2BUGS(imputations, statistic = c("moments", "imputations", "parameters"))
```

Arguments

```
imputations an object of mi-class
statistic single character string among "moments", "imputations", and "parameters" indicating what statistic to monitor for convergence
```

Details

If statistic = "moments" (the default), then the mean and standard deviation of each variable will be monitored over the iterations. If statistic = "imputations", then the imputed values will be monitored, which may be quite large and quite slow and is not possible if the save_RAM = TRUE flag was set in the call to the mi function. If statistic = "parameters", then the estimated coefficients and ancillary parameters extracted by the get_parameters-methods will be monitored.

Rhats produces a vector of R-hat convergence statistics that compare the variance between chains to the variance across chains. Values closer to 1.0 indicate little is to be gained by running the chains longer, and in general, values greater than 1.1 indicate that the chains should be run longer. See Gelman, Carlin, Stern, and Rubin, "Bayesian Data Analysis", Second Edition, 2009, p.304 for more information about the R-hat statistic.

mi 2BUGS outputs the history of the indicated statistic

Value

mi 2BUGS returns an array while Rhats a vector of R-hat convergence statistics.

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

Examples

```
if(!exists("imputations", env = .GlobalEnv)) {
  imputations <- mi:::imputations # cached from example("mi-package")
}
  dim(mi2BUGS(imputations))
  Rhats(imputations)</pre>
```

18 06pool

\sim	_		_		п
a	b	n	\sim	റ	- 1

Estimate a Model Pooling Over the Imputed Datasets

Description

This function estimates a chosen model, taking into account the additional uncertainty that arises due to a finite number of imputations of the missing data.

Usage

```
pool(formula, data, m = NULL, FUN = NULL, ...)
```

Arguments

formula	a formula in the same syntax as used by glm
data	an object of mi-class
m	number of completed datasets to average over, which if NULL defaults to the number of chains used in \min
FUN	Function to estimate models or NULL which uses the same function as used in the $fit_model-methods$ for the dependent variable
	further arguments passed to FUN

Details

FUN is estimated on each of the m completed datasets according to the given formula and the results are combined using the Rubin Rules.

Value

An object of class "pooled" whose definition is subject to change but it has a summary and display method.

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

mi

07complete 19

Examples

07complete

Extract the Completed Data

Description

This function extracts several multiply imputed data. frames from an object of mi-class.

Usage

```
complete(y, m, ...)
```

Arguments

An object of mi-class (typically) or missing_data.frame-class or missing_variable-class

If y is an object of mi-class, then m must be a specified integer indicating how many multiply imputed data.frames to return or, if missing, the number of data.frames will be equal to the length of the data slot in y. If y is not an object of mi-class, then m must be a specified integer indicating which iteration to use in the resulting data.frame, where any non-positive integer is a short hand for the last iteration.

Other arguments, not currently utilized

Details

Several functions within **mi** use complete, although the only reason in principle why a user should need to call complete is to create data. frames to export to another program. For analysis, it is better to use the pool function, although currently pool might not offer all the necessary functionality.

Value

If y is an object of mi-class and m > 1, a list of m data. frames is returned. Otherwise, a single data. frame is returned.

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

```

```
allcategorical_missing_data.frame

Class "allcategorical_missing_data.frame"
```

Description

This class inherits from the missing_data. frame-class but is customized for the situation where all the variables are categorical.

Details

The fit_model-methods for the allcategorical_missing_data.frame class implement a Gibbs sampler. However, it does not utilize any ordinal information that may be available. Continuous variables should be made into factors using the cut command before calling missing_data.frame.

Objects from the Class

Objects can be created by calls of the form new("allcategorical_missing_data.frame", ...). However, its users almost always will pass a data.frame to the missing_data.frame function and specify the subclass argument.

Slots

The allcategorical_missing_data.frame class inherits from the missing_data.frame-class and has three additional slots

Hstar Positive integer indicating the maximum number of latent classes

parameters A list that holds the current realization of the unknown parameters

latents An object of unordered-categorical-class that contains the current realization of the latent classes

Author(s)

Sophie Si for the algorithm and Ben Goodrich for the R implementation

bounded-continuous-class 21

See Also

```
missing_data.frame
```

Examples

bounded-continuous-class

Class "bounded-continuous"

Description

The bounded-continuous class inherits from the continuous-class and is intended for variables whose observations fall within open intervals that have *known* boundaries. Although proportions satisfy this definition, the proportion-class should be used in that case. At the moment, a bounded continuous variable is modeled as if it were simply a continuous variable, but its mi-methods impute the missing values from a truncated normal distribution using the rtruncnorm function in the **truncnorm** package. Note that the default transformation is the identity so if another transformation is used, the bounds must be specified on the transformed data. Aside from these facts, the rest of the documentation here is primarily directed toward developers.

Objects from the Classes

Objects can be created that are of bounded-continuous class via the the missing_variable generic function by specifying type = "bounded-continuous" as well as lower and / or upper

Slots

The bounded-continuous class inherits from the continuous class and is intended for variables that are supported on a known interval. Its default transformation function is the identity transformation and its imputation_method must be "ppd". It has two additional slots:

upper a numeric vector whose length is either one or the value of the n_total slot giving the upper bound for *every* observation; NAs are not allowed

lower a numeric vector whose length is either one or the value of the n_total slot giving the lower bound for *every* observation; NAs are not allowed

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

missing_variable, continuous-class, positive-continuous-class, proportion-class

22 categorical

Examples

categorical

Class "categorical" and Inherited Classes

Description

The categorical class is a virtual class that inherits from the missing_variable-class and is the parent of the unordered-categorical and ordered-categorical classes. The ordered-categorical class is the parent of both the binary and interval classes. Aside from these facts, the rest of the documentation here is primarily directed toward developers.

Objects from the Classes

The categorical class is virtual, so no objects may be created from it. However, the missing_variable generic function can be used to instantiate an object that inherits from the categorical class by specifying type = "unordered-categorical", type = "ordered-categorical", type = "binary", type = "grouped-binary", or type = "interval".

Slots

The unordered-categorical class inherits from the categorical class and has no additional slots but must have more than two uniquely observed values in its raw_data slot. The default fit_model method is a wrapper for the multinom function in the **nnet** package. The ordered-categorical class inherits from the categorical class and has one additional slot:

cutpoints Object of class "numeric" which is a vector of thresholds (sometimes estimated) that govern how an assumed latent variable is divided into observed ordered categories

The fit_model method for an ordered-categorical variable is, by default, a wrapper for bayespolr. The binary class inherits from the ordered-categorical class and has no additional slots. It must have exactly two uniquely observed values in its raw_data slot and its fit_model method is, by default, a wrapper for bayespolr. The grouped-binary class inherits from the binary class and has one additional slot:

strata Object of class "character" which is a vector (possibly of length one) of variable names that group the observations into strata. The named external variables should also be categorical.

censored-continuous-class 23

The default fit_model method for a grouped-binary variable is a wrapper for the clogit function in the **survival** package and the variables named in the **strata** slot are passed to the **strata** function.

The interval class inherits from the ordered-categorical class, has no additional slots, and is intended for variables whose observed values are only known up to orderable intervals. Its fit_model method is, by default, a wrapper for survreg even though it may or may not be a "survival" model in any meaningful sense.

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

Examples

```
# STEP 0: GET DATA
data(nlsyV, package = "mi")

# STEP 0.5 CREATE A missing_variable (you never need to actually do this)
momrace <- missing_variable(as.factor(nlsyV$momrace), type = "unordered-categorical")
show(momrace)</pre>
```

```
censored-continuous-class
```

The "censored-continuous" Class, the "truncated-continuous" Class and Inherited Classes

Description

The censored-continuous class and the truncated-continuous class are both virtual and both inherit from the continuous-class and each is the parent of four classes that differ depending on whether the lower and upper bounds are numeric vectors or functions. A censored observation is one whose exact value is not observed. A truncated observation is one whose exact value is not observed and which implies that values on some *other* variables are not observed for that unit of observation. An example of truncation might be that some taxation forms are not required when a person's income falls below a certain threshold. The methods for these classes are not working yet. Aside from these facts, the rest of the documentation here is primarily directed toward developeRs.

Objects from the Classes

Both the censored-continuous class and the truncated-continuous class are virtual, so no objects can be created with these classes. However, the missing_variable generic function can be used to create an object that inherits from one of their subclasses by specifying type = "NNcensored-continuous", type = "FNcensored-continuous", type = "FNcensored-continuous", type = "NNtruncated-continuous", type = "NNtruncated-continuous", type = "NFtruncated-continuous", type = "FNtruncated-continuous",

24 censored-continuous-class

type = "FFtruncated-continuous". When doing so, the lower and upper slots need to be specified appropriately.

Slots

The censored-continuous class and the truncated-continuous class are both virtual, both inherit from the continuous class, both use the identity transformation by default, and both have two additional slots:

upper The upper bound for each observation

lower The lower bound for each observation

Both the censored-continuous class and the truncated-continuous class have four subclasses that differ depending on whether the upper and / or lower bounds are numeric vectors or functions that output numeric vectors (scalars are recycled and can be Inf). These subclasses are

NN censored-continuous where both the lower and upper bounds are numeric vectors

FN_censored-continuous where the lower bound is a function and the upper bound is a numeric vector

NF_censored-continuous where the lower bound is a numeric vector and the upper bound is a function

FF_censored-continuous where both the lower and upper bounds are functions

NN_truncated-continuous where both the lower and upper bounds are numeric vectors

FN_truncated-continuous where the lower bound is a function and the upper bound is a numeric vector

NF_truncated-continuous where the lower bound is a numeric vector and the upper bound is a function

FF_truncated-continuous where both the lower and upper bounds are functions

Author(s)

Ben Goodrich, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

# lower = 0, upper = Inf)
#show(log_virus)</pre>
```

CHAIN 25

CHAIN

Subset of variables from the CHAIN project

Description

The CHAIN project was a longitudinal cohort study of people living with HIV in New York City, which was recruited in 1994 from a large number of medical care and social service agencies serving HIV in New York City. This subset of data pertain to the sixth round of interviews.

Usage

data(CHAIN)

Format

A data. frame with 532 observations on the following 8 variables.

log_virus log of self reported viral load level, where zero represents an undetectable level.

age age at time of the interview

income annual family income in 10 intervals

healthy a continuous scale of physical health with a theoretical range between 0 and 100 where better health is associated with higher scale values

mental a binary measure of poor mental health (1=Yes, 0=No)

damage ordered interval for the CD4 count, which is an indicator of how much damage HIV has caused to the immune system

treatment a three-level ordered variable: 0=Not currently taking HAART (Highly Active AntiretRoviral Therapy) 1=taking HAART but nonadherent, 2=taking HAART and adherent

Details

A missing value in the log virus load level was assigned to individuals who either could not recall their viral load level, did not have a viral load test in the six month preceding the interview, or reported their viral loads as "good" or "bad".

26 continuous

continuous

Class "continuous"

Description

The continuous class inherits from the missing_variable-class and is the parent of the following classes: semi-continuous, censored-continuous, truncated-continuous, and bounded-continuous. The distinctions among these subclasses are given on their respective help pages. Aside from these facts, the rest of the documentation here is primarily directed toward developers.

Objects from the Classes

Objects can be created that are of class continuous via the missing_variable generic function by specifying type = "continuous"

Slots

The continuous class inherits from the missing_variable class and has the following additional slots:

transformation Object of class "function" which is passed the raw_data slot and whose returned value is assigned to the data slot. By default, this function is the "standardize" transformation, using the mean and *twice* the standard deviation of the observed values

inverse_transformation Object of class "function" which is the inverse of the function in the transformation slot.

transformed Object of class "logical" of length one indicating whether the data slot is in the "transformed" state or the "untransformed" state

known_transformations Object of class "character" indicating which transformations are possible for this variable

The fit_model method for a continuous variable is, by default, a wrapper for bayesglm and its family slot is, by default, gaussian

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

Examples

```
# STEP 0: GET DATA
data(nlsyV, package = "mi")

# STEP 0.5 CREATE A missing_variable (you never need to actually do this)
income <- missing_variable(nlsyV$income, type = "continuous")
show(income)</pre>
```

count-class

Class "count"

Description

The count class inherits from the missing_variable-class and is intended for count data. Aside from these facts, the rest of the documentation here is primarily directed toward developers.

Objects from the Classes

Objects can be created that are of count class via the missing_variable generic function by specifying type = "count"

Slots

The count class inherits from the missing_variable class and its raw_data slot must consist of nonnegative integers. Its default family is quasipoisson and its default fit_model method is a wrapper for bayesglm. The other possibility for the family is poisson but is not recommended due to its overly-restrictive nature.

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

# STEP 0.5 CREATE A missing_variable (you never need to actually do this)
age <- missing_variable(as.integer(CHAIN$age), type = "count")
show(age)</pre>
```

Description

This class inherits from the missing_data.frame-class but is customized for the situation where the sample is a randomized experiment.

Details

The fit_model-methods for the experiment_missing_data.frame class take into account the special nature of a randomized experiment. At the moment, the treatment variable must be binary and fully observed.

Objects from the Class

Objects can be created by calls of the form new("experiment_missing_data.frame", ...). However, its users almost always will pass a data.frame to the missing_data.frame function and specify the subclass and concept arguments.

Slots

The experiment_missing_data.frame class inherits from the missing_data.frame-class and has two additional slots

concept Object of class factor whose length is equal to the number of variables and whose levels are "treatment", "covariate" and "outcome"

case Object of class character of length one, indicating whether the missingness is in the outcomes only, in the covariates only, or in both the outcomes and covariates. This slot is filled automatically by the initialize method

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

fit_model 29

fit_model

Wrappers To Fit a Model

Description

The methods are called by the mi function to model a given missing_variable as a function of all the other missing_variables and also their missingness pattern. By overwriting these methods, users can change the way a missing_variable is modeled for the purposes of imputing its missing values. See also the table in missing_variable.

Usage

```
fit_model(y, data, ...)
```

Arguments

```
y An object that inherits from missing_variable-class or missing data A missing_data.frame
... Additional arguments, not currently utilized
```

Details

In mi, each missing_variable is modeled as a function of all the other missing_variables plus their missingness pattern. The fit_model methods are typically short wrappers around a statistical model fitting function and return the estimated model. The model is then passed to one of the mi-methods to impute the missing values of that missing_variable.

Users can easily overwrite these methods to estimate a different model, such as wrapping glm instead of bayesglm. See the source code for examples, but the basic outline is to first extract the X slot of the missing_data.frame, then drop some of its columns using the index slot of the missing_data.frame, next pass the result along with the data slot of y to a statistical fitting function, and finally returned the appropriately classed result (along with the subset of X used in the model).

Many of the optional arguments to a statistical fitting function can be specified using the slots of y (e.g. its family slot) or the slots of **data** (e.g. its weights slot).

The exception is the method where y is missing, which is used internally by mi, and should *not* be overwritten unless great care is taken to understand its role.

Value

If y is missing, then the modified missing_data. frame passed to data is returned. Otherwise, the estimated model is returned as a classed list object.

30 get_parameters

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

```
missing_variable, mi, get_parameters
```

Examples

```
getMethod("fit_model", signature(y = "binary", data = "missing_data.frame"))
setMethod("fit_model", signature(y = "binary", data = "missing_data.frame"), def =
function(y, data, ...) {
 to_drop <- data@index[[y@variable_name]]</pre>
 X <- data@X[, -to_drop]</pre>
 start <- NULL
 # using glm.fit() instead of bayesglm.fit()
 out <- glm.fit(X, y@data, weights = data@weights[[y@variable_name]], start = start,</pre>
                 family = y@family, Warning = FALSE, ...)
 outx < - X
 class(out) <- c("glm", "lm") # not "bayesglm" class anymore</pre>
 return(out)
})
## Not run:
if(!exists("imputations", env = .GlobalEnv)) {
 imputations <- mi:::imputations # cached from example("mi-package")</pre>
imputations <- mi(imputations) # will use new fit_model() method for binary variables
## End(Not run)
```

get_parameters

An Extractor Function for Model Parameters

Description

This function is not intended to be called directly by users. During the multiple imputation process, the mi function estimates models and stores the estimated parameters in the parameters slot of an object that inherits from the missing_variable-class. The get_parameter function simply extracts these parameters for storeage, which are usually the estimated coefficients but may also include ancillary parameters.

Usage

```
get_parameters(object, ...)
```

Arguments

```
object Usually an estimated model, such as that produced by glm
... Additional arguments, currently not used
```

hist 31

Details

There is method for the object produced by polr, which also returns the estimated cutpoints in a proportional odds model. However, the default method simply calls coef and returns the result. If users implement their own models, it may be necessary to write a short get_parameters method.

Value

A numeric vector of estimated parameters

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

See Also

```
fit_model
```

Examples

```
showMethods("get_parameters")
```

hist

Histograms of Multiply Imputed Data

Description

This function creates a histogram from an object of missing_data.frame-class or mi-class

Usage

```
hist(x, ...)
```

Arguments

```
x an object of missing_data.frame-class or mi-class
... further arguments passed to plot.histogram
```

Details

When called on an object of missing_data.frame-class, the histograms of the observed data are generated, one for each missing_variable but grouped on a single page. When called on an object of mi-class, the histograms of the observed, imputed, and completed data are generated, one for each missing_variable, grouped on a single page for each chain.

Value

An invisible NULL is returned with a side-effect of creating a plot

32 irrelevant

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

  imputations <- mi:::imputations # cached from example("mi-package")
}
hist(imputations)</pre>
```

irrelevant

Class "irrelevant" and Inherited Classes

Description

The irrelevant class inherits from the missing_variable-class and is used to designate variables that are excluded from the models used to impute the missing values of "relevant" variables. For example, if a survey has an "id" variable that simply distinguishes observations, the user should designate it as irrelevant, although it will automatically be classified so if its name is either "id" or starts with punctuation (including underscores). The fixed class inherits from the irrelevant class and is used for variables that are constant (within a sample). A variable that is instantiated from the fixed class cannot have any missing values. The group class inherits from the fixed class and is used like a factor to spit samples in multilevel modeling; see multilevel_missing_data.frame-class. None of these classes have an additional slots. Aside from these facts, the rest of the documentation here is primarily directed toward developeRs.

Objects from the Classes

The missing_variable generic function can be used to instantiate an object that inherits from the irrelevant class by specifying type = "irrelevant", type = "fixed", or type = "group".

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

mi2stata

Exports completed data in Stata (.dta) or comma-separated (.csv) format

Description

This function exports completed data from an object of mi-class in which m completed data. frames are appended to the end of the raw data. Two additional variables are added which indicate the row number and distinguish the data. frames. The outputed file is either Stata (.dta) or commaseparated (.csv) format, and can be easily registered in Stata as multiply imputed data.

Usage

```
mi2stata(imputations, m, file, missing.ind=FALSE, ...)
```

Arguments

imputations	Object of mi-class
m	The number of completed datasets to append onto the raw data
file	The filename, either a full path or relative to the working directory, where the file will be saved. Filenames must end in either '.dta' or '.csv'. Files with names ending in '.dta' will be saved as a Stata data file, and files with names ending in '.csv' will be saved as a comma-separated file.
missing.ind	If TRUE, includes a binary variable for each variable with NA values, indicating the observations which were originally missing. Defaults to FALSE.
•••	Further arguments passed to write.dta for Stata files, or to write.table for .csv files.

Details

The function calls complete to construct m completed data.frames, and uses rbind to append them to the bottom of the raw data that still contains all of the missing values. Two new variables are added: _mi, which contains the observation numbers; and _mj, which indexes the data.frames.

To save a Stata .dta file, end the filename with '.dta'. To save a comma-separated file, end the filename with .csv'. Stata files are loaded into Stata using Stata's use command, and comma-separated files can be loaded by typing insheet using *filename*, comma names clear. Once the file is loaded into Stata, the data must be registered as multiply imputed before any subsequent analyses can be performed. In Stata version 11 or later, type mi import mice to register the data.

34 mipply

The _mi and _mj variables will be replaced by variables named _mi_id and _mi_m respectively. In Stata version 10 or earlier, install the MIM package by typing findit mim and installing package st0139_1. Then the prefix mim: must be added to any command using the multiply imputed data.

Any observations which are unpossible (legitimately skipped, and are not imputed, see missing_variable) will remain missing in the complete data, but will not be indicated as missing by these variables. If there are any unpossible values, missing indicators are included automatically.

Value

NULL

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

}
mi2stata(imputations, m=5, file=fn , missing.ind=TRUE)</pre>
```

mipply

Apply a Function to a Object of Class mi

Description

This function is a wrapper around sapply that is invoked on the data slot of an object of mi-class and / or on an object of missing_data.frame-class after being coerced to a data.frame

Usage

Arguments

simplify	If TRUE, coerces result to a vector or matrix if possible
USE.NAMES	ignored but included for compatibility with sapply
columnwise	logical indicating whether to invoke FUN on the columns of a missing_data.frame after coercing it to a data.frame or a matrix or to invoke FUN on the "whole" data.frame or matrix
to.matrix	Logical indicating whether to coerce each missing_data.frame to a numeric matrix or to a data.frame. The default is FALSE, in which case the data.frame will include factors if any of the missing_variables inherit from categorical-class

Details

The columnwise and to.matrix arguments are the only additions to the argument list in sapply, see the Examples section for an illustration of their use. Note that functions such as mean only accept numeric inputs, which can produce errors or warnings when to.matrix = FALSE.

Value

A list, vector, or matrix depending on the arguments

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

mipply(imputations, summary, columnwise = FALSE)</pre>
```

```
multilevel_missing_data.frame

Class "multilevel_missing_data.frame"
```

Description

This class inherits from the missing_data. frame-class but is customized for the situation where the sample has a multilevel structure.

36 multinomial

Details

The fit_model-methods for the multilevel_missing_data.frame class will, by default, utilize multilevel modeling techniques that shrink the estimated parameters for each group toward their global means.

Objects from the Class

Objects can be created by calls of the form new("multilevel_missing_data.frame", ...). However, its users almost always will pass a data.frame to the missing_data.frame function and specify the subclass and groups arguments.

Slots

The multilevel_missing_data.frame class inherits from the missing_data.frame-class and has two additional slots

groups Object of class character indicating which variables define the multilevel structure
mdf_list Object of class mdf_list whose elements contain a missing_data.frame for each group.
 This slot is filled automatically by the initialize method.

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

multinomial

The multinomial family

Description

This function is a returns a family and is a generalization of binomial. users would only need to call it when calling change with what = "family", to = multinomial(link = 'logit')

Usage

```
multinomial(link = "logit")
```

Arguments

link

character string among those supported by binomial

nlsyV 37

Details

This function is mostly cosmetic. The family slot for an object of unordered-categorical-class must be multinomial(link = 'logit'). For an object of ordered-categorical-class but not its subclasses, the family slot must be multinomial() but the link function can differ from its default ("logit")

Value

A family object

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

nlsyV

National Longitudinal Survey of Youth Extract

Description

This dataset pertains to children and their families in the United States and is intended to illustrate missing data issues. Note that although the original data are longitudinal, this extract is not.

Usage

```
data(nlsyV)
```

Format

A data frame with 400 randomly subsampled observations on the following 7 variables.

ppvtr.36 a numeric vector with data on the Peabody Picture Vocabulary Test (Revised) administered at 36 months

first indicator for whether child was first-born

b.marr indicator for whether mother was married when child was born

income a numeric vector with data on family income in year after the child was born

momage a numeric vector with data on the age of the mother when the child was born

momed educational status of mother when child was born (1 = less than high school, 2 = high school graduate, 3 = some college, 4 = college graduate)

```
momrace race of mother (1 = black, 2 = Hispanic, 3 = white)
```

Note that **momed** would typically be an ordered factor while **momrace** would typically be an unorderd factor but both are numeric in this data. frame in order to illustrate the mechanism to change the type of a missing_variable

Examples

```
data(nlsyV)
summary(nlsyV)
```

```
positive-continuous-class
```

Class "positive-continuous" and Inherited Classes

Description

The positive-continuous class inherits from the continuous-class and is the parent of the proportion class. In both cases, no observations can be zero, and in the case of the proportion class, no observations can be one. The nonnegative-continuous-class and the SC_proportion-class are appropriate for those situations. Aside from these facts, the rest of the documentation here is primarily directed toward developeRs.

Objects from the Classes

Objects can be created that are of positive-continuous or proportion class via the missing_variable generic function by specifying type = "positive-continuous" or type = "proportion"

Slots

The default transformation for the positive-continuous class is the log function. The proportion class inherits from the positive-continuous class and has the identity transformation and the binomial family as defaults, in which case the fit_model-methods call the betareg function in the betareg package. Alternatively, the transformation could be an inverse CDF like the qnorm function and the family could be gaussian, in which case the fit_model-methods call the bayesglm function in the arm package.

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.

show(healthy)</pre>
```

rdata.frame

Generate a random data.frame with tunable characteristics

Description

This function generates a random data. frame with a missingness mechanism that is used to impose a missingness pattern. The primary purpose of this function is for use in simulations

Usage

```
rdata.frame(N = 1000,
    restrictions = c("none", "MARish", "triangular", "stratified", "MCAR"),
    last_CPC = NA_real_, strong = FALSE, pr_miss = .25, Sigma = NULL,
    alpha = NULL, experiment = FALSE,
    treatment_cor = c(rep(0, n_full - 1), rep(NA, 2 * n_partial)),
    n_full = 1, n_partial = 1, n_cat = NULL,
    eta = 1, df = Inf, types = "continuous", estimate_CPCs = TRUE)
```

Arguments

N	integer indicating the number of observations
restrictions	character string indicating what restrictions to impose on the the missing data mechansim, see the Details section
last_CPC	a numeric scalar between -1 and 1 exclusive or NA_real_ (the default). If not NA_real_, then this value will be used to construct the correlation matrix from which the data are drawn. This option is useful if restrictions is "triangular" or "stratified", in which case the degree to which last_CPC is not zero causes a violation of the Missing-At-Random assumption that is confined to the last of the partially observed variables
strong	Integer among 0, 1, and 2 indicating how strong to make the instruments with multiple partially observed variables, in which case the missingness indicators for each partially observed variable can be used as instruments when predicting missingness on other partially observed variables. Only applies when restrictions = "triangular"
pr_miss	numeric scalar on the $(0,1)$ interval or vector of length n_partial indicating the proportion of observations that are missing on partially observed variables

40 rdata.frame

Sigma Either NULL (the default) or a correlation matrix of appropriate order for the

variables (including the missingness indicators). By default, such a matrix is

generated at random.

alpha Either NULL, NA, or a numeric vector of appropriate length that governs the skew

of a multivariate skewed normal distribution; see rmsn. The appropriate length is $n_full - 1 + 2 * n_partial$ iff none of the variable types is nominal. If some of the variable types are nominal, then the appropriate length is $n_{full} - 1 + 2$ * n_partial + sum(n_cat) - length(n_cat). If NULL, alpha is taken to be zero, in which case the data-generating process has no skew. If NA, alpha is

drawn from rt with df degrees of freedom

experiment logical indicating whether to simulate a randomized experiment

treatment_cor Numeric vector of appropriate length indicating the correlations between the

treatment variable and the other variables, which is only relevant if experiment = TRUE. The appropriate length is $n_full - 1 + 2 * n_partial$ iff none of the variable types is nominal. If some of the variable types are nominal, then the appropriate length is $n_{full} - 1 + 2 * n_{partial} + sum(n_{cat}) - length(n_{cat})$. If treatment_cor is of length one and is zero, then it will be recylced to the appropriate length. The treatment variable should be uncorrelated with intended covariates and uncorrelated with missingness on intended covariates. If any elements of treatment_cor are NA, then those elements will be replaced with random draws. Note that the order of the random variables is: all fully observed variables, all partially observed but not nominal variables, all partially observed

nominal variables, all missingness indicators for partially observed variables.

integer indicating the number of fully observed variables n_full

integer indicating the number of partially observed variables n_partial

Either NULL or an integer vector (possibly of length one) indicating the number n_cat

of categories in each partially observed nominal or ordinal variable; see the

Details section

eta Positive numeric scalar which serves as a hyperparameter in the data-generating

process. The default value of 1 implies that the correlation matrix among the variables is jointly uniformally distributed, using essentially the same logic as

in the clusterGeneration package

df positive numeric scalar indicating the degress of freedom for the (possibly skewed)

multivariate t distribution, which defaults to Inf implying a (possibly skewed)

multivariate normal distribution

a character vector (possibly of length one, in which case it is recycled) indicating

the type for each fully observed and partially observed variable, which currently can be among "continuous", "count", "binary", "treatment" (which is binary), "ordinal", "nominal", "proportion", "positive". See the Details

section. Unique abbreviations are acceptable.

A logical indicating whether the canonical partial correlations between the partially observed variables and the latent missingnesses should be estimated. The

default is TRUE but considerable wall time can be saved by switching it to FALSE

when there are many partially observed variables.

types

estimate_CPCs

rdata.frame 41

Details

By default, the correlation matrix among the variables and missingness indicators is intended to be close to uniform, although it is often not possible to achieve exactly. If restrictions = "none", the data will be Not Missing At Random (NMAR). If restrictions = "MARish", the departure from Missing At Random (MAR) will be minimized via a call to optim, but generally will not fully achieve MAR. If restrictions = "triangular", the MAR assumption will hold but the missingness of each partially observed variable will only depend on the fully observed variables and the other latent missingness indicators. If restrictions = "stratified", the MAR assumption will hold but the missingness of each partially observed variable will only depend on the fully observed variables. If restrictions = "MCAR", the Missing Completely At Random (MCAR) assumption holds, which is much more restrictive than MAR.

There are some rules to follow, particularly when specifying types. First, if experiment = TRUE, there must be exactly one treatment variable (taken to be binary) and it must come first to ensure that the elements of treatment_cor are handled properly. Second, if there are any partially observed nominal variables, they must come last; this is to ensure that they are conditionally uncorrelated with each other. Third, fully observed nominal variables are not supported, but they can be made into ordinal variables and then converted to nominal after the fact. Fourth, including both ordinal and nominal partially observed variables is not supported yet, Finally, if any variable is specified as a count, it will not be exactly consistent with the data-generating process. Essentially, a count variable is constructed from a continuous variable by evaluating pt on it and passing that to qpois with an intensity parameter of 5. The other non-continuous variables are constructed via some transformation or discretization of a continuous variable.

If some partially observed variables are either ordinal or nominal (but not both), then the n_cat argument governs how many categories there are. If n_cat is NULL, then the number of categories defaults to three. If n_cat has length one, then that number of categories will be used for all categorical variables but must be greater than two. Otherwise, the length of n_cat must match the number of partially observed categorical variables and the number of categories for the *i*th such variable will be the *i*th element of n_cat.

Value

A list with the following elements:

- 1. true a data. frame containing no NA values
- obs a data. frame derived from the previous with some NA values that represents a dataset that could be observed
- 3. empirical_CPCs a numeric vector of empirical Canonical Partial Correlations, which should differ only randomly from zero iff MAR = TRUE and the data-generating process is multivariate normal
- 4. L a Cholesky factor of the correlation matrix used to generate the true data

In addition, if alpha is not NULL, then the following elements are also included:

- 1. alpha the alpha vector utilized
- 2. sn_skewness the skewness of the multivariate skewed normal distribution in the population; note that this value is only an approximation of the skewness when df < Inf
- 3. sn_kurtosis the kurtosis of the multivariate skewed normal distribution in the population; note that this value is only an approximation of the kurtosis when df < Inf

print(round(Sigma, 3))
```

semi-continuous-class Class "semi-continuous" and Inherited Classes

Description

The semi-continuous class inherits from the continuous-class and is the parent of the nonnegative-continuous class, which in turn is the parent of the SC_proportion class for semi-continuous variables. A semi-continuous variable has support on one or more point masses and a continuous interval. The semi-continuous class differs from the censored-continuous-class and the truncated-continuous-class in that observations that fall on the point masses are bonafide data, rather than indicators of censoring or truncation. If there are no observations that fall on a point mass, then either the continuous-class or one of its other subclasses should be used. Aside from these facts, the rest of the documentation here is primarily directed toward developers.

Objects from the Classes

Objects can be created that are of semi-continuous, nonnegative-continuous, or SC_proportion class via the missing_variable generic function by specifying type = "semi-continuous" type = "nonnegative-continuous", type = "SC_proportion".

semi-continuous-class 43

Slots

The semi-continuous class inherits from the continuous class and is intended for variables that, for example have a point mass at certain points and are continuous in between. Thus, its default transformation is the identity transformation, which is to say no transformation in practice. It has one additional slot.

indicator Object of class "ordered-categorical" that indicates whether an observed value falls on a point mass or the continuous interval in between. By convention, zero signifies an observation that falls within the continuous interval

At the moment, there are no methods for the semi-continuous class. However, the basic approach to modeling a semi-continuous variable has two steps. First, the **indicator** is modeled using the methods that are defined for it and its missing values are imputed. Second, the continuous part of the semi-continuous variable is modeled using the same techniques that are used when modeling continuous variables. Note that in the second step, only a subset of the observations are modeled, although this subset possibly includes values that were originally missing in which case they are imputed.

The nonnegative-continuous class inherits from the semi-continuous class, which has its point mass at zero and is continuous over the positive real line. By default, the transformation for the positive part of a nonnegative-continuous variable is log(y + a), where a is a small constant determined by the observed data. If a variable is strictly positive, the positive-continuous-class should be used instead.

The SC_proportion class inherits from the nonnegative-continuous class. It has no additional slots, and the only supported transformation function is the (y * (n - 1) + .5) / n function. Its default fit_model method is a wrapper for the betareg function in the betareg package. Its family must be binomial so that its link function can be passed to betareg If the observed values fall strictly on the open unit interval, the proportion-class should be used instead.

Author(s)

Ben Goodrich and Jonathan Kropko, for this version, based on earlier versions written by Yu-Sung Su, Masanao Yajima, Maria Grazia Pittau, Jennifer Hill, and Andrew Gelman.
