Package 'rplum'

June 2, 2021

Type Package

Title Bayesian Age-Depth Modelling of Cores Dated by Pb-210

Version 0.2.2

Date 2021-06-02

Description An approach to age-depth modelling that uses Bayesian statistics to reconstruct accumulation histories for 210Pb-dated deposits using prior information. It can combine 210Pb, radiocarbon, and other dates in the chronologies. See Aquino et al. (2018) <doi:10.1007/s13253-018-0328-7>. Note that parts of the code underlying 'rplum' are derived from the 'rbacon' package by the same authors, and there remains a degree of overlap between the two packages.

Plum   *Main 210Pb age-depth modelling function*

Description

This is the main age-depth modelling function of the rplum package for 210Pb age-modelling.

Usage

```
Plum(
  core = "HP1C",
  thick = 1,
  otherdates = NA,
  coredir = "",
  phi.shape = 2,
  phi.mean = 50,
  s.shape = 5,
  s.mean = 10,
  Al = 0.1,
  date.sample = c(),
  n.supp = c(),
  ra.case = c(),
  Bqkg = TRUE,
  seed = NA,
  prob = 0.95,
  d.min = 0,
  d.max = NA,
  d.by = 1,
  depths.file = FALSE,
  depths = c(),
  depth.unit = "cm",
  age.unit = "yr",
  unit = depth.unit,
  acc.shape = 1.5,
  acc.mean = 10,
  mem.strength = 10,
  mem.mean = 0.5,
  boundary = NA,
  hiatus.depths = NA,
```

```
      hiatus.max = 10000,
      add = c(),
      after = 1e-04/thick,
      cc = 1,
      cc1 = "IntCal20",
      cc2 = "Marine20",
      cc3 = "SHCal20",
      cc4 = "ConstCal",
      ccdir = "",
      postbomb = 0,
      delta.R = 0,
      delta.STD = 0,
      t.a = 3,
      t.b = 4,
      normal = FALSE,
      suggest = TRUE,
      reswarn = c(10, 200),
      remember = TRUE,
      ask = TRUE,
      run = TRUE,
      defaults = "defaultPlum_settings.txt",
      sep = ",",
      dec = ".",
      runname = "",
      slump = c(),
      BCAD = FALSE,
      ssize = 2000,
      th0 = c(),
      burnin = min(1500, ssize),
      MinAge = c(),
      MaxAge = c(),
      cutoff = 0.001,
      rounded = 1,
      plot.pdf = TRUE,
      dark = 1,
      date.res = 100,
      age.res = 200,
      close.connections = TRUE,
      verbose = TRUE,
      ...
  )
```

Arguments

core   Name of the core, given using quotes. Defaults to one of the cores provided
                with rplum, core="HP1C" also reported by Aquino-Lopez et al. (2018). Also
                available is LL14, a core kindly provided by Dr Lysanna Anderson (USGS).
                LL14 has ra-226 data (so can be run with ra.case=1 or ra.case=2, see be-
                low), and also has additional C-14 and cal BP data (these can be added using

	otherdates="LL14_14C.csv"). The original LL14 core has more 14C data than provided here (for reasons of brevity). To run your own core, produce a .csv file with the dates as outlined in the manual, add a folder with the core's name to the default directory for cores (see coredir), and save the .csv file there. For example, the file's location and name could be Plum_runs/MyCore/MyCore.csv. Then run Plum as follows: Plum("MyCore"). Note that for Pb-210 data, the depth in the .csv should be the bottom of the slice, not the mid-point. (For any non-Pb data, depths are the midpoints of their slices). Also make sure that the thickness and density are given correctly for each Pb-210 data point.
thick	Plum will divide the core into sections of equal thickness specified by thick (default thick=1).
otherdates	Name of (optional) file with radiocarbon dates. This file should have the same format as the one used for rbacon. For example, Bacon("LL14",otherdates="LL14_14C.csv").
coredir	Folder where the core's files core are and/or will be located. This will be a folder with the core's name, within either the folder coredir='Plum_runs/', or the folder Cores/ if it already exists within R's working directory, or a custom-built folder. For example, use coredir="." to place the core's folder within the current working directory, or coredir="F:" if you want to put the core's folder and files on a USB drive loaded under F:. Thinner (and thus more) sections will result in smoother age-models, but too many sections can cause 'run-away' models.
phi.shape	Shape parameter of the prior gamma distribution used for the influx of Pb-210 to the sediment, default phi.shape=2.
phi.mean	Mean parameter of the prior gamma distribution used for the influx of Pb-210 to the sediment, default phi.mean=50.
s.shape	Shape parameter of the prior gamma distribution used for the supported Pb-210 to the sediment, default s.shape=5.
s.mean	Mean parameter of the prior gamma distribution used for the supported Pb-210 to the sediment, default s.mean=10.
Al	Parameter used to limit the chronologies described in Aquino-Lopez et al. (2018) for the minimum distinguishable unsupported activity; default Al=0.1.
date.sample	Date at which the core was measured for Pb-120. This date will be used as a surface date and is assumed to have no uncertainty, date.sample=NA. If the date is not provided (in the .csv file or as date.sample), Plum will ask for it.
n.supp	This value will delete n.supp data points from the deepest part of the core, and these points will then be used exclusively to estimate the supported activity. If this option is used, a constant supported Pb-210 will be assumed, n.supp=-1.
ra.case	How to use radium-226 measurements if they are provided in the core's .csv file. 1 = assume constant radium, 2 = assume varying radium and use the radium measurements as individual estimates of supported Pb-210. If no radium measurements are present, use ra.case=0.
Bqkg	This variable indicates whether total Pb-210 is expressed in Bq/kg (default; Bqkg=TRUE) or dpm/g if set to FALSE.
seed	Seed used for C++ executions; if it is not assigned then the seed is set by system. Default seed=NA.

prob	Confidence interval to report. This should lie between 0 and 1, default `prob=0.95` (95 %).
d.min	Minimum depth of age-depth model (use this to extrapolate to depths higher than the top dated depth).
d.max	Maximum depth of age-depth model (use this to extrapolate to depths below the bottom dated depth).
d.by	Depth intervals at which ages are calculated. Defaults to `d.by=1`.
depths.file	By default, Plum will calculate the ages for the depths `d.min` to `d.max` in steps of `d.by`. If `depths.file=TRUE`, Plum will read a file containing the depths for which you require ages. This file, containing the depths in a single column without a header, should be stored within `coredir`, and its name should start with the core's name and end with '_depths.txt'. Then specify `depths.file=TRUE` (default `FALSE`). See also `depths`.
depths	By default, Plum will calculate the ages for the depths `d.min` to `d.max` in steps of `d.by`. Alternative depths can be provided as, e.g., `depths=seq(0,100,length=500)` or as a file, e.g., `depths=read.table("CoreDepths.txt"`. See also `depths.file`
depth.unit	Units of the depths. Defaults to `depth.unit="cm"`.
age.unit	Units of the ages. Defaults to `age.unit="yr"`.
unit	Deprecated and replaced by `depth.unit`.
acc.shape	The prior for the accumulation rate consists of a gamma distribution with two parameters. Its shape is set by acc.shape (default `acc.shape=1.5`; higher values result in more peaked shapes).
acc.mean	The accumulation rate prior consists of a gamma distribution with two parameters. Its mean is set by acc.mean (default `acc.mean=10` yr/cm (or whatever age or depth units are chosen), which can be changed to, e.g., 5, 10 or 50 for different kinds of deposits). Multiple values can be given in case of hiatuses or boundaries, e.g., Plum(hiatus.depths=23, acc.mean=c(5,20))
mem.strength	The prior for the memory (dependence of accumulation rate between neighbouring depths) is a beta distribution, which looks much like the gamma distribution. but its values are always between 0 (no assumed memory) and 1 (100% memory). Its default settings of `mem.strength=10` (higher values result in more peaked shapes) allow for a large range of posterior memory values.
mem.mean	The prior for the memory is a beta distribution, which looks much like the gamma distribution but its values are always between 0 (no assumed memory) and 1 (100% memory). Its default settings of `mem.mean=0.5` allow for a large range of posterior memory values.
boundary	The assumed depths of any boundary, which divides sections of different accumulation rate regimes (e.g., as indicated by major change in the stratigraphy). No hiatus is assumed between these sections, and memory is reset crossing the boundary. Different accumulation priors can be set for the sections above and below the boundary, e.g., `acc.mean=c(5,20)`. See also `hiatus.depths`, `mem.mean`, `acc.mean` and `acc.shape`. Setting many boundaries might not work, and having more than one boundary per model section (see `'thick'`) might not work either.

hiatus.depths	The assumed depths for any hiatus should be provided as, e.g., hiatus.depths=20 for one at 20cm depth, and hiatus.depths=c(20,40) for two hiatuses at 20 and 40 cm depth.
hiatus.max	The prior for the maximum length of the hiatus. Hiatus length is a uniform distribution, with equal probabilities between 0 and hiatus.max yr (or whatever other age.unit is chosen).
add	Add a value to the maximum hiatus length if a boundary is chosen. Defaults to 100 yr (or whatever other age unit is chosen). Can be adapted if Plum complains that the parameters are out of support.
after	Sets a short section above and below hiatus.depths within which to calculate ages. For internal calculations - do not change.
cc	Calibration curve for C-14 dates: cc=1 for IntCal20 (northern hemisphere terrestrial), cc=2 for Marine20 (marine), cc=3 for SHCal20 (southern hemisphere terrestrial). For dates that are already on the cal BP scale use cc=0.
cc1	For northern hemisphere terrestrial 14C dates (IntCal20).
cc2	For marine 14C dates (Marine20).
cc3	For southern hemisphere 14C dates (SHCal20).
cc4	Use an alternative curve (3 columns: cal BP, 14C age, error, separated by white spaces and saved as a plain-text file). See ccdir.
ccdir	Directory where the calibration curves for C14 dates cc are located. By default ccdir="" since they are loaded into R's memory. For example, use ccdir="." to choose current working directory, or ccdir="Curves/" to choose sub-folder Curves/. Note that all calibration curves should reside in the same directory. If you want to add a custom-built curve, put it in the directory where the default calibration curves are (probably list.files(paste0(.libPaths(),"/IntCal/extdata/"))). Alternatively produce a new folder, and add your curve as well as the default calibration curves there (cc1, cc2 and cc3; e.g., write.table(copyCalibrationCurve(1),"./3Col_intca
postbomb	Use a postbomb curve for negative (i.e. postbomb) 14C ages. 0 = none, 1 = NH1, 2 = NH2, 3 = NH3, 4 = SH1-2, 5 = SH3
delta.R	Mean of core-wide age offsets (e.g., regional marine offsets).
delta.STD	Error of core-wide age offsets (e.g., regional marine offsets).
t.a	The dates are treated using the student's t distribution by default (normal=FALSE). The student's t-distribution has two parameters, t.a and t.b, set at 3 and 4 by default (see Christen and Perez, 2010). If you want to assign narrower error distributions (more closely resembling the normal distribution), set t.a and t.b at for example 33 and 34 respectively (e.g., for specific dates in your .csv file). For symmetry reasons, t.a must always be equal to t.b-1.
t.b	The dates are treated using the student's t distribution by default (normal=FALSE). The student's t-distribution has two parameters, t.a and t.b, set at 3 and 4 by default (see Christen and Perez, 2010). If you want to assign narrower error distributions (more closely resembling the normal distribution), set t.a and t.b at for example 33 and 34 respectively (e.g., for specific dates in your .csv file). For symmetry reasons, t.a must always be equal to t.b-1.

normal	By default, Plum uses the student's t-distribution to treat the dates. Use normal=TRUE to use the normal/Gaussian distribution. This will generally give higher weight to the dates.
suggest	If initial analysis of the data indicates abnormally slow or fast accumulation rates, Plum will suggest to change the prior. Also, if the length of the core would cause too few or too many sections with the default settings, Plum will suggest an alternative section thickness thick, and it will suggest approaches to estimating supported Pb-120. Accept these suggested alternative settings by typing "y" (or "yes please" if you prefer to be polite), or leave as is by typing "n" (or anything else, really). To get rid of these suggestions, use suggest=FALSE.
reswarn	Plum will warn you if the number of sections lies outside the safe range (default between 10 and 200 sections; reswarn=c(10,200)). Too few sections could lead to an 'elbowy' model while with too many sections the modelling process can get lost, resulting in age-models far away from the dated depths.
remember	Plum will try to remember which settings you have applied to your cores (default remember=TRUE). If you run into inconsistencies or other problems, try running your core again with remember=FALSE, or, start cleanly by typing Plum.cleanup().
ask	By default Plum will ask you to confirm that you want to run the core with the provided settings. Disable this using ask=FALSE (e.g., for batch runs).
run	In order to load an existing Plum run instead of producing a new one, you can use run=FALSE.
defaults	Name of the file containing settings for the core. For internal use only - do not change.
sep	Separator between the fields of the plain text file containing the dating information. Default sep=",".
dec	Character for decimal points. Default to dec=".".
runname	Text to add to the corename for specific runs, e.g., runname="MyCore_Test1".
slump	Upper and lower depths of any sections of assumed abrupt accumulation, that require excising before age-modelling (and adding after age-modelling). Requires pairs of depths, e.g., slump=c(10,15,60,67) for slumps at 67-60 and 15-10 cm core depth.
BCAD	The calendar scale of graphs and age output-files is in cal BP (calendar or calibrated years before the present, where the present is AD 1950) by default, but can be changed to BC/AD using BCAD=TRUE.
ssize	The approximate amount of iterations to store at the end of the MCMC run. Default 2000; decrease for faster (but less reliable) runs or increase for cores where the MCMC mixing (panel at upper-left corner of age-model graph) appears problematic.
th0	Starting years for the MCMC iterations.
burnin	Amount of initial, likely sub-optimal MCMC iterations that will be removed.
MinAge	Minimum age limit for Plum runs, default at current year in cal BP. To set plot limits, use yr.min instead.
MaxAge	Maximum age limit for Plum runs, default at 1,000,000 cal BP. To set plot limits, use yr.max instead.

cutoff	Avoid plotting very low probabilities of date distributions (default `cutoff=0.001`).
rounded	Rounding of calendar years. Defaults to 1 decimal.
plot.pdf	Produce a pdf file of the age-depth plot. Defaults to `plot.pdf=TRUE` after a Plum run.
dark	Darkness of the greyscale age-depth model. The darkest grey value is `dark=1` by default. Lower values will result in lighter grey but values >1 are not allowed.
date.res	Date distributions are plotted using `date.res=100` segments by default.
age.res	Resolution or amount of greyscale pixels to cover the age scale of the age-model plot. Default `yr.res=200`.
close.connections	
	Internal option to close connections after a run. Default `close.connections=TRUE`.
verbose	Provide feedback on what is happening (default `verbose=TRUE`).
...	options for the age-depth graph. See [agedepth](#) and [calib.plot](#)

Details

Plum is an approach to age-depth modelling that uses Bayesian statistics in order to reconstruct accumulation histories for 210Pb-dated deposits by taking into account prior information, and can combine 210Pb, radiocarbon and other dates (Aquino et al. 2018).

Plum handles 210Pb and other dated depths within in a core, by dividing a core into many thin vertical sections (by default of `thick=1` cm thickness), and through millions of Markov Chain Monte Carlo (MCMC) iterations estimates the flux of 210Pb and supported 210Pb, as well as the accumulation rate (in years/cm; so more correctly, sedimentation times) for each of these sections. Combined with an estimated starting date for the first section, these accumulation rates and values for 210Pb then form the age-depth and 210Pb model. The accumulation rates are constrained by prior information on the accumulation rate (`acc.mean,acc.shape`) and its variability between neighbouring depths, or "memory" (`mem.mean,mem.strength`). Hiatuses can be introduced as well, also constrained by prior information (`hiatus.max`). The 210Pb flux (phi) and supported 210Pb (s) are constrained by priors `phi.mean,phi.shape,s.mean` and `s.shape`.

Although Plum was developed for 210Pb dates, it can also include absolute dates (e.g., 14C, OSL, tephra or other dates on a calendar scale). Radiocarbon dates should be calibrated using either IntCal20 (for terrestrial northern hemisphere material; Reimer et al., 2020), Marine20 (for marine dates; Hughen et al., 2020), SHCal20 (for southern hemisphere dates; Hogg et al., 2020) or any other calibration curve (see below), while modern 14C dates are calibrated using one of the post-bomb calibration curves (NH1, NH2 or NH3 for the northern hemisphere, SH1-2 or SH3 for the southern hemisphere; Hua et al., 2013). See <http://calib.org/CALIBomb/> if you are unsure which postbomb curve you need. If Plum finds postbomb dates (negative 14C ages) and you haven't specified a postbomb curve, you will be prompted. Provide postbomb curves as, e.g., `postbomb=1` for the NH1 postbomb curve (2 for NH2, 3 for NH3, 4 for SH1-2, 5 for SH3).

For calendar dates, i.e. dates that are already on the calendar scale and thus should not be calibrated, `setcc=0`. Plum also needs the date of sampling, in AD (`date.sample`).

Value

An age-depth model graph, its age estimates, and a summary.

Examples

```
Plum(ask=FALSE, run=FALSE, coredir=tempfile(), date.sample=2018.5, ra.case=0, n.supp=3)
agedepth(age.res=50, d.res=50)
```

Plum.cleanup *Remove files made to produce the current core's age-depth model.*

Description

Remove files .bacon, .out, .pdf, _ages.txt, and _settings.txt of current core.

Usage

```
Plum.cleanup(set = get("info"))
```

Arguments

set   Detailed information of the current run, stored within this session's memory as variable info.

Details

If cores behave badly, you can try cleaning up previous runs and settings, by removing files .bacon, .out, .pdf, _ages.txt, and _settings.txt of current core.

Value

A message stating that the files and settings of this run have been deleted.

Author(s)

Maarten Blaauw, J. Andres Christen

Plum_runs   *List the folders present in the current core directory.*

Description

Lists all folders located within the core's directory.

Usage

```
Plum_runs(coredir = get("info")$coredir)
```

Arguments

coredir   The directory where the Bacon runs reside. Defaults to `coredir="Plum_runs"`.

Details

The directory is either "Plum_runs", "Cores" or a custom-named one.

Value

A list of folders
