Package 'survPen'

September 11, 2021

Title Multidimensional Penalized Splines for Survival and Net Survival Models

Version 1.5.2

Author Mathieu Fauvernier [aut, cre], Laurent Roche [aut], Laurent Remontet [aut], Zoe Uhry [ctb], Nadine Bossard [ctb]

Maintainer Mathieu Fauvernier <mathieu.fauvernier@gmail.com>

Description

Fits hazard and excess hazard models with multidimensional penalized splines allowing for time-dependent effects, non-linear effects and interactions between several continuous covariates. In survival and net survival analysis, in addition to modelling the effect of time (via the baseline hazard), one has often to deal with several continuous covariates and model their functional forms, their time-dependent effects, and their interactions. Model specification becomes therefore a complex problem and penalized regression splines represent an appealing solution to that problem as splines offer the required flexibility while penalization limits overfitting issues. Current implementations of penalized survival models can be slow or unstable and sometimes lack some key features like taking into account expected mortality to provide net survival and excess hazard estimates. In contrast, survPen provides an automated, fast, and stable implementation (thanks to explicit calculation of the derivatives of the likelihood) and offers a unified framework for multidimensional penalized hazard and excess hazard models, survPen may be of interest to those who 1) analyse any kind of time-to-event data: mortality, disease relapse, machinery breakdown, unemployment, etc 2) wish to describe the associated hazard and to understand which predictors impact its dynamics.

See Fauvernier et al. (2019a) <doi:10.21105/joss.01434> for an overview of the package and Fauvernier et al. (2019b) <doi:10.1111/rssc.12368> for the method.

colSums2

colSums2

colSums of a matrix

Description

colSums of a matrix

Usage

```
colSums2(Mat)
```

Arguments

Mat

a matrix.

Value

colSums(Mat)

constraint

Sum-to-zero constraint

Description

Applies the sum-to-zero constraints to design and penalty matrices.

Usage

```
constraint(X, S, Z = NULL)
```

Arguments

- X A design matrix
- S A penalty matrix or a list of penalty matrices
- Z A list of sum-to-zero constraint matrices; default is NULL

Value

List of objects with the following items:

- X Design matrix
- S Penalty matrix or list of penalty matrices
- Z List of sum-to-zero constraint matrices

4 crs

Examples

```
library(survPen)
set.seed(15)

X <- matrix(rnorm(10*3),nrow=10,ncol=3)
S <- matrix(rnorm(3*3),nrow=3,ncol=3) ; S <- 0.5*( S + t(S))

# applying sum-to-zero constraint to a desgin matrix and a penalty matrix constr <- constraint(X,S)</pre>
```

cor.var

Implementation of the corrected variance Vc

Description

Takes the model at convergence and calculates the variance matrix corrected for smoothing parameter uncertainty

Usage

```
cor.var(model)
```

Arguments

model

survPen object, see survPen.fit for details

Value

survPen object with corrected variance Vc

crs

Bases for cubic regression splines (equivalent to "cr" in mgcv)

Description

Builds the design matrix and the penalty matrix for cubic regression splines.

```
crs(x, knots = NULL, df = 10, intercept = TRUE)
```

crs.FP 5

Arguments

knots Numeric vectors that specifies the knots of the splines (including boundaries);

default is NULL

df numeric value that indicates the number of knots desired (or degrees of freedom)

if knots=NULL; default is 10

intercept if FALSE, the intercept is excluded from the basis; default is TRUE

Details

See package mgcv and section 4.1.2 of Wood (2006) for more details about this basis

Value

List of three elements

bs design matrix pen penalty matrix

knots vector of knots (specified or calculated from df)

References

Wood, S. N. (2006), Generalized additive models: an introduction with R. London: Chapman & Hall/CRC.

Examples

```
x <- seq(1,10,length=100)
# natural cubic spline with 3 knots
crs(x,knots=c(1,5,10))</pre>
```

crs.FP

Penalty matrix constructor for cubic regression splines

Description

constructs the penalty matrix associated with cubic regression splines basis. This function is called inside crs.

```
crs.FP(knots, h)
```

6 datCancer

Arguments

knots Numeric vectors that specifies the knots of the splines (including boundaries)

h vector of knots differences (corresponds to diff(sort(knots)))

Value

List of two elements:

F.mat matrix used in function crs for basis construction

P.mat penalty matrix

Examples

```
library(survPen)

# construction of the penalty matrix using a sequence of knots
knots <- c(0,0.25,0.5,0.75,1)
diff.knots <- diff(knots)

crs.FP(knots,diff.knots)</pre>
```

datCancer

Patients diagnosed with cervical cancer

Description

A simulated dataset containing the follow-up times of 2000 patients diagnosed with cervical cancer between 1990 and 2010. End of follow-up is June 30th 2013. The variables are as follows:

- begin. beginning of follow-up. For illustration purposes about left truncation only (0–1)
- fu. follow-up time in years (0–5)
- age. age at diagnosis in years, from 21.39 to 99.33
- yod. decimal year of diagnosis, from 1990.023 to 2010.999
- dead. censoring indicator (1 for dead, 0 for censored)
- rate. expected mortality rate (from overall mortality of the general population) (0–0.38)

Usage

```
data(datCancer)
```

Format

A data frame with 2000 rows and 6 variables

deriv_R

deriv_R

Derivative of a Choleski factor

Description

Derivative of a Choleski factor

Usage

```
deriv_R(deriv_Vp, p, R1)
```

Arguments

deriv_Vp derivatives of the Bayesian covariance matrix wrt rho (log smoothing parameters).

p number of regression parameters

R1 Choleski factor of Vp

Value

a list containing the derivatives of R1 wrt rho (log smoothing parameters)

design.matrix

Design matrix for the model needed in Gauss-Legendre quadrature

Description

Builds the design matrix for the whole model when the sum-to-zero constraints are specified. The function is called inside model.cons for Gauss-Legendre quadrature.

```
design.matrix(
  formula,
  data.spec,
  Z.smf,
  Z.tensor,
  Z.tint,
  list.smf,
  list.tensor,
  list.tint,
  list.rd
)
```

8 design.matrix

Arguments

formula	formula object identifying the model
data.spec	data frame that represents the environment from which the covariate values and knots are to be calculated
Z.smf	List of matrices that represents the sum-to-zero constraint to apply for \ensuremath{smf} splines
Z.tensor	List of matrices that represents the sum-to-zero constraint to apply for tensor splines
Z.tint	List of matrices that represents the sum-to-zero constraint to apply for \mbox{tint} splines
list.smf	List of all smf.smooth.spec objects contained in the model
list.tensor	List of all tensor.smooth.spec objects contained in the model
list.tint	List of all tint.smooth.spec objects contained in the model
list.rd	List of all rd.smooth.spec objects contained in the model

Value

design matrix for the model

Examples

```
library(survPen)
# standard spline of time with 4 knots
data <- data.frame(time=seq(0,5,length=100),event=1,t0=0)</pre>
form \leftarrow smf(time,knots=c(0,1,3,5))
t1 <- eval(substitute(time), data)</pre>
t0 <- eval(substitute(t0), data)</pre>
event <- eval(substitute(event), data)</pre>
# Setting up the model
model.c <- model.cons(form,lambda=0,data.spec=data,t1=t1,t1.name="time",</pre>
t0=rep(0,100),t0.name="t0",event=event.name="event",
expected=NULL, expected.name=NULL, type="overall", n.legendre=20,
cl="survPen(form,data,t1=time,event=event)",beta.ini=NULL)
# Retrieving the sum-to-zero constraint matrices and the list of knots
Z.smf <- model.c$Z.smf ; list.smf <- model.c$list.smf</pre>
# Calculating the design matrix
design.M <- design.matrix(form,data.spec=data,Z.smf=Z.smf,list.smf=list.smf,</pre>
Z.tensor=NULL,Z.tint=NULL,list.tensor=NULL,list.tint=NULL,list.rd=NULL)
```

grad_rho 9

grad_rho Graters	adient vector of LCV and LAML wrt rho (log smoothing parame-
------------------	--

Description

Gradient vector of LCV and LAML wrt rho (log smoothing parameters)

Usage

```
grad_rho(
 X_GL,
 GL_temp,
 haz_GL,
 deriv_rho_beta,
 weights,
  tm,
  nb_smooth,
 n_legendre,
 S_list,
  {\tt temp\_LAML},
  ۷p,
  S_beta,
 beta,
  inverse_new_S,
 Χ,
  temp_deriv3,
  event,
  expected,
  type,
  Vе,
 mat_temp,
 method
)
```

Arguments

X_GL	list of matrices (length(X.GL)=n.legendre) for Gauss-Legendre quadrature
GL_temp	list of vectors used to make intermediate calculations and save computation time
haz_GL	list of all the matrix-vector multiplications $X.GL[[i]]\%*\%$ beta for Gauss Legendre integration in order to save computation time
deriv_rho_beta	firt derivative of beta wrt rho (implicit differentiation)
weights	vector of weights for Gauss-Legendre integration on [-1;1]
tm	vector of midpoints times for Gauss-Legendre integration; $tm = 0.5*(t1 - t0)$

10 Hess_rho

nb_smooth number of smoothing parameters
p number of regression parameters

n_legendre number of nodes for Gauss-Legendre quadrature

S_list List of all the rescaled penalty matrices multiplied by their associated smoothing

parameters

temp_LAML temporary matrix used when method="LAML" to save computation time

Vp Bayesian covariance matrix

S_beta List such that S_beta[[i]]=S_list[[i]]%*%beta beta vector of estimated regression parameters

inverse_new_S inverse of the penalty matrix
X design matrix for the model

temp_deriv3 temporary matrix for third derivatives calculation when type="net" to save com-

putation time

event vector of right-censoring indicators
expected vector of expected hazard rates

type "net" or "overall"

Ve frequentist covariance matrix

mat_temp temporary matrix used when method="LCV" to save computation time

method criterion used to select the smoothing parameters. Should be "LAML" or "LCV";

default is "LAML"

Value

List of objects with the following items:

grad_rho gradient vector of LCV or LAML

deriv_rho_inv_Hess_beta

List of first derivatives of Vp wrt rho

deriv_rho_Hess_unpen_beta

List of first derivatives of the Hessian of the unpenalized log-likelihood wrt rho

Hess_rho Hessian matrix of LCV and LAML wrt rho (log smoothing parameters)

Description

Hessian matrix of LCV and LAML wrt rho (log smoothing parameters)

Hess_rho 11

Usage

```
Hess_rho(
 X_GL,
  X_GL_Q,
 GL_temp,
 haz_GL,
  deriv2_rho_beta,
  deriv_rho_beta,
 weights,
  tm,
  nb_smooth,
  p,
  n_legendre,
  deriv_rho_inv_Hess_beta,
  deriv_rho_Hess_unpen_beta,
  S_list,
  minus_eigen_inv_Hess_beta,
  temp_LAML,
  temp_LAML2,
  ۷p,
  S_beta,
  beta,
  inverse_new_S,
 Χ,
 X_Q,
  temp_deriv3,
  temp_deriv4,
  event,
  expected,
  type,
  ۷e,
  deriv_rho_Ve,
 mat_temp,
  deriv_mat_temp,
  eigen_mat_temp,
  method
)
```

Arguments

X_GL	list of matrices (length(X.GL)=n.legendre) for Gauss-Legendre quadrature
X_GL_Q	list of transformed matrices from X_GL in order to calculate only the diagonal
	of the fourth derivative of the likelihood
GL_temp	list of vectors used to make intermediate calculations and save computation time
haz_GL	list of all the matrix-vector multiplications X.GL[[i]]%*%beta for Gauss Leg-
	endre integration in order to save computation time
deriv2_rho_beta	

second derivatives of beta wrt rho (implicit differentiation)

12 Hess_rho

deriv_rho_beta firt derivatives of beta wrt rho (implicit differentiation)
weights vector of weights for Gauss-Legendre integration on [-1;1]

tm vector of midpoints times for Gauss-Legendre integration; tm = 0.5*(t1 - t0)

nb_smooth number of smoothing parameters
p number of regression parameters

n_legendre number of nodes for Gauss-Legendre quadrature

deriv_rho_inv_Hess_beta

list of first derivatives of Vp wrt rho

deriv_rho_Hess_unpen_beta

list of first derivatives of Hessian of unpenalized log likelihood wrt rho

S_list List of all the rescaled penalty matrices multiplied by their associated smoothing

parameters

minus_eigen_inv_Hess_beta

vector of eigenvalues of Vp

temp_LAML temporary matrix used when method="LAML" to save computation time temp_LAML2 temporary matrix used when method="LAML" to save computation time

Vp Bayesian covariance matrix

S_beta List such that S_beta[[i]]=S_list[[i]]%*%beta beta vector of estimated regression parameters

inverse_new_S inverse of the penalty matrix X design matrix for the model

X_Q transformed design matrix in order to calculate only the diagonal of the fourth

derivative of the likelihood

temp_deriv3 temporary matrix for third derivatives calculation when type="net" to save com-

putation time

temp_deriv4 temporary matrix for fourth derivatives calculation when type="net" to save

computation time

event vector of right-censoring indicators expected vector of expected hazard rates

type "net" or "overall"

Ve frequentist covariance matrix deriv_rho_Ve list of derivatives of Ve wrt rho

mat_temp temporary matrix used when method="LCV" to save computation time

deriv_mat_temp list of derivatives of mat_temp wrt rho eigen_mat_temp vector of eigenvalues of mat_temp

method criterion used to select the smoothing parameters. Should be "LAML" or "LCV";

default is "LAML"

Value

Hessian matrix of LCV or LAML wrt rho

instr 13

instr

Position of the nth occurrence of a string in another one

Description

Returns the position of the nth occurrence of str2 in str1. Returns 0 if str2 is not found

Usage

```
instr(str1, str2, startpos = 1, n = 1)
```

Arguments

str1 main string in which str2 is to be found

str2 substring contained in str1

startpos starting position in str1; default is 1

n which occurrence is to be found; default is 1

Value

number representing the nth position of str2 in str1

Examples

```
library(survPen) instr("character test to find the position of the third letter r","r",n=3)
```

inv.repam

Reverses the initial reparameterization for stable evaluation of the log determinant of the penalty matrix

Description

Transforms the final model by reversing the initial reparameterization performed by repam. Derives the corrected version of the Bayesian covariance matrix

```
inv.repam(model, X.ini, S.pen.ini)
```

14 model.cons

Arguments

```
model survPen object, see survPen.fit for details

X.ini initial design matrix (before reparameterization)

S.pen.ini initial penalty matrices
```

Value

survPen object with standard parameterization

model.cons

Design and penalty matrices for the model

Description

Sets up the model before optimization. Builds the design matrix, the penalty matrix and all the design matrices needed for Gauss-Legendre quadrature.

Usage

```
model.cons(
  formula,
  lambda,
  data.spec,
  t1,
  t1.name,
  t0,
  t0.name,
  event,
  event.name,
  expected,
  expected.name,
  type,
  n.legendre,
  cl,
  beta.ini
)
```

Arguments

formula formula object identifying the model

lambda vector of smoothing parameters

data spec data frame that represents the environment from which the covariate values and knots are to be calculated

t1 vector of follow-up times t1.name name of t1 in data.spec model.cons 15

vector of origin times (usually filled with zeros)

t0.name name of t0 in data.spec
event vector of censoring indicators
event.name name of event in data.spec
expected vector of expected hazard

expected.name name of expected in data.spec

type "net" or "overall"

n. legendre number of nodes for Gauss-Legendre quadrature

cl original survPen call

beta.ini initial set of regression parameters

Value

List of objects with the following items:

cl original survPen call type "net" or "overall"

n.legendre number of nodes for Gauss-Legendre quadrature

n number of individuals
p number of parameters

X.para design matrix associated with fully parametric parameters (unpenalized)

X. smooth design matrix associated with the penalized parameters

X design matrix for the model

leg list of nodes and weights for Gauss-Legendre integration on [-1;1] as returned

by gauss.quad

X.GL list of matrices (length(X.GL)=n.legendre) for Gauss-Legendre quadrature

S penalty matrix for the model. Sum of the elements of S.list

S. scale vector of rescaling factors for the penalty matrices

rank.S rank of the penalty matrix

S.F balanced penalty matrix as described in section 3.1.2 of (Wood,2016). Sum of

the elements of S.F.list

U.F Eigen vectors of S.F, useful for the initial reparameterization to separate penal-

ized ad unpenalized subvectors. Allows stable evaluation of the log determinant

of S and its derivatives

S. smf List of penalty matrices associated with all "smf" calls
S. tensor List of penalty matrices associated with all "tensor" calls
S. tint List of penalty matrices associated with all "tint" calls
S. rd List of penalty matrices associated with all "rd" calls

smooth.name.smf

List of names for the "smf" calls associated with S.smf

16 model.cons

smooth.name.te	smooth.name.tensor	
	List of names for the "tensor" calls associated with S.tensor	
smooth.name.ti		
	List of names for the "tint" calls associated with S.tint	
smooth.name.rd	List of names for the "rd" calls associated with S.rd	
S.pen	List of all the rescaled penalty matrices redimensioned to df.tot size. Every element of pen noted pen[[i]] is made from a penalty matrix returned by $smooth.cons$ and is multiplied by the factor S.scale=norm(X,type="I")^2/norm(pen[[i]],type="I")	
S.list	Equivalent to S.pen but with every element multiplied by its associated smoothing parameter	
S.F.list	Equivalent to S.pen but with every element divided by its Frobenius norm	
lambda	vector of smoothing parameters	
df.para	degrees of freedom associated with fully parametric terms (unpenalized)	
df.smooth	degrees of freedom associated with penalized terms	
df.tot	df.para + df.smooth	
list.smf	List of all smf.smooth.spec objects contained in the model	
list.tensor	List of all tensor.smooth.spec objects contained in the model	
list.tint	List of all tint.smooth.spec objects contained in the model	
nb.smooth	number of smoothing parameters	
Z.smf	List of matrices that represents the sum-to-zero constraints to apply for smf splines	
Z.tensor	List of matrices that represents the sum-to-zero constraints to apply for tensor splines	
Z.tint	List of matrices that represents the sum-to-zero constraints to apply for tint splines	
beta.ini	initial set of regression parameters	

Examples

```
library(survPen)

# standard spline of time with 4 knots

data <- data.frame(time=seq(0,5,length=100),event=1,t0=0)

form <- ~ smf(time,knots=c(0,1,3,5))

t1 <- eval(substitute(time), data)
t0 <- eval(substitute(t0), data)
event <- eval(substitute(event), data)

# The following code sets up everything we need in order to fit the model
model.c <- model.cons(form,lambda=0,data.spec=data,t1=t1,t1.name="time",
t0=rep(0,100),t0.name="t0",event=event,event.name="event",</pre>
```

NR.beta 17

```
expected=NULL,expected.name=NULL,type="overall",n.legendre=20,
cl="survPen(form,data,t1=time,event=event)",beta.ini=NULL)
```

NR.beta	Inner Newton-Raphson algorithm for regression parameters estima-
	tion

Description

Applies Newton-Raphson algorithm for beta estimation. Two specific modifications aims at guaranteeing convergence: first the hessian is perturbed whenever it is not positive definite and second, at each step, if the penalized log-likelihood is not maximized, the step is halved until it is.

Usage

```
NR.beta(build, beta.ini, detail.beta, max.it.beta = 200, tol.beta = 1e-04)
```

Arguments

build	list of objects returned by model.cons
beta.ini	vector of initial regression parameters; default is NULL, in which case the first beta will be log(sum(event)/sum(t1)) and the others will be zero (except if there are "by" variables in which case all betas are set to zero)
detail.beta	if TRUE, details concerning the optimization process in the regression parameters are displayed; default is FALSE
max.it.beta	maximum number of iterations to reach convergence in the regression parameters; default is 200
tol.beta	convergence tolerance for regression parameters; default is 1e-04

Details

If we note 11.pen and beta respectively the current penalized log-likelihood and estimated parameters and 11.pen.old and betaold the previous ones, the algorithm goes on while (abs(ll.pen-ll.pen.old)>tol.beta) or any(abs((beta-betaold)/betaold)>tol.beta)

Value

List of objects:

beta	estimated regression parameters
ll.unpen	log-likelihood at convergence
ll.pen	penalized log-likelihood at convergence
haz.GL	list of all the matrix-vector multiplications $X.GL[[i]]\%*\%$ beta for Gauss Legendre integration. Useful to avoid repeating operations in $survPen.fit$
iter.beta	number of iterations needed to converge

NR.rho

Examples

```
library(survPen)
# standard spline of time with 4 knots

data <- data.frame(time=seq(0,5,length=100),event=1,t0=0)

form <- ~ smf(time,knots=c(0,1,3,5))

t1 <- eval(substitute(time), data)
t0 <- eval(substitute(t0), data)
event <- eval(substitute(event), data)

# Setting up the model before fitting
model.c <- model.cons(form,lambda=0,data.spec=data,t1=t1,t1.name="time",
t0=rep(0,100),t0.name="t0",event=event,event.name="event",
expected=NULL,expected.name=NULL,type="overall",n.legendre=20,
cl="survPen(form,data,t1=time,event=event)",beta.ini=NULL)

# Estimating the regression parameters at given smoothing parameter (here lambda=0)
Newton1 <- NR.beta(model.c,beta.ini=rep(0,4),detail.beta=TRUE)</pre>
```

NR.rho

Outer Newton-Raphson algorithm for smoothing parameters estimation via LCV or LAML optimization

Description

Applies Newton-Raphson algorithm for smoothing parameters estimation. Two specific modifications aims at guaranteeing convergence: first the hessian is perturbed whenever it is not positive definite and second, at each step, if LCV or -LAML is not minimized, the step is halved until it is.

```
NR.rho(
  build,
  rho.ini,
  data,
  formula,
  max.it.beta = 200,
  max.it.rho = 30,
  beta.ini = NULL,
  detail.rho = FALSE,
  detail.beta = FALSE,
  nb.smooth,
  tol.beta = 1e-04,
```

NR.rho

```
tol.rho = 1e-04,
  step.max = 5,
  method = "LAML"
)
```

Arguments

build	list of objects returned by model.cons
rho.ini	vector of initial log smoothing parameters; if it is NULL, all log lambda are set to -1 $$
data	an optional data frame containing the variables in the model
formula	formula object specifying the model
max.it.beta	maximum number of iterations to reach convergence in the regression parameters; default is 200
max.it.rho	maximum number of iterations to reach convergence in the smoothing parameters; default is 30
beta.ini	vector of initial regression parameters; default is NULL, in which case the first beta will be log(sum(event)/sum(t1)) and the others will be zero (except if there are "by" variables in which case all betas are set to zero)
detail.rho	if TRUE, details concerning the optimization process in the smoothing parameters are displayed; default is FALSE
detail.beta	if TRUE, details concerning the optimization process in the regression parameters are displayed; default is FALSE
nb.smooth	number of smoothing parameters
tol.beta	convergence tolerance for regression parameters; default is 1e-04
tol.rho	convergence tolerance for smoothing parameters; default is 1e-04
step.max	maximum absolute value possible for any component of the step vector (on the log smoothing parameter scale); default is 5
method	LCV or LAML; default is LAML

Details

If we note val the current LCV or LAML value, val.old the previous one and grad the gradient vector of LCV or LAML with respect to the log smoothing parameters, the algorithm goes on while(abs(val-val.old)>tol.rho|any(abs(grad)>tol.rho))

Value

```
object of class survPen (see survPen.fit for details)
```

Examples

```
library(survPen)
# standard spline of time with 4 knots
```

20 predict.survPen

```
data <- data.frame(time=seq(0,5,length=100),event=1,t0=0)

form <- ~ smf(time,knots=c(0,1,3,5))

t1 <- eval(substitute(time), data)
 t0 <- eval(substitute(t0), data)
 event <- eval(substitute(event), data)

# Setting up the model before fitting
model.c <- model.cons(form,lambda=0,data.spec=data,t1=t1,t1.name="time",
t0=rep(0,100),t0.name="t0",event=event,event.name="event",
expected=0,expected.name=NULL,type="overall",n.legendre=20,
cl="survPen(form,data,t1=time,event=event)",beta.ini=NULL)

# Estimating the smoothing parameter and the regression parameters
# we need to apply a reparameterization to model.c before fitting
Newton2 <- NR.rho(repam(model.c)$build,rho.ini=-1,data,form,nb.smooth=1,detail.rho=TRUE)</pre>
```

predict.survPen

Hazard and Survival prediction from fitted survPen model

Description

Takes a fitted survPen object and produces hazard and survival predictions given a new set of values for the model covariates.

Usage

```
## S3 method for class 'survPen'
predict(
   object,
   newdata,
   newdata.ref = NULL,
   n.legendre = 50,
   conf.int = 0.95,
   do.surv = TRUE,
   type = "standard",
   exclude.random = FALSE,
   get.deriv.H = FALSE,
   ...
)
```

Arguments

object a fitted survPen object as produced by survPen.fit newdata data frame giving the new covariates value

predict.survPen 21

newdata.ref	data frame giving the new covariates value for the reference population (used only when type="HR")
n.legendre	number of nodes to approximate the cumulative hazard by Gauss-Legendre quadrature; default is 50
conf.int	numeric value giving the precision of the confidence intervals; default is 0.95
do.surv	If TRUE, the survival and its lower and upper confidence values are computed. Survival computation requires numerical integration and can be time-consuming so if you only want the hazard use do.surv=FALSE; default is TRUE
type,	if type="lpmatrix" returns the design matrix (or linear predictor matrix) corresponding to the new values of the covariates; if equals "HR", returns the predicted HR and CIs between newdata and newdata.ref; default is "standard" for classical hazard and survival estimation
${\tt exclude.random}$	if TRUE all random effects are set to zero; default is FALSE
get.deriv.H	if TRUE, the derivatives wrt to the regression parameters of the cumulative hazard are returned; default is FALSE
	other arguments

Details

The confidence intervals noted CI.U are built on the log cumulative hazard scale U=log(H) (efficient scale in terms of respect towards the normality assumption) using Delta method. The confidence intervals on the survival scale are then CI.surv = exp(-exp(CI.U))

Value

List of objects:

haz	hazard predicted by the model
haz.inf	lower value for the confidence interval on the hazard based on the Bayesian covariance matrix Vp (Wood et al. 2016)
haz.sup	Upper value for the confidence interval on the hazard based on the Bayesian covariance matrix Vp
surv	survival predicted by the model
surv.inf	lower value for the confidence interval on the survival based on the Bayesian covariance matrix Vp
surv.sup	Upper value for the confidence interval on the survival based on the Bayesian covariance matrix Vp
deriv.H	derivatives wrt to the regression parameters of the cumulative hazard. Useful to calculate standardized survival
HR	predicted hazard ratio; only when type = "HR"
HR.inf	lower value for the confidence interval on the hazard ratio based on the Bayesian covariance matrix Vp ; only when $type = "HR"$
HR.sup	Upper value for the confidence interval on the hazard ratio based on the Bayesian covariance matrix Vp; only when type = "HR"

```

print.summary.survPen print summary for a survPen fit

Description

print summary for a survPen fit

```
## S3 method for class 'summary.survPen'
print(
    x,
    digits = max(3, getOption("digits") - 2),
    signif.stars = getOption("show.signif.stars"),
    ...
)
```

rd 23

Arguments

x an object of class summary.survPen
 digits controls number of digits printed in output.
 signif.stars Should significance stars be printed alongside output.

... other arguments

Value

print of summary

rd

Defining random effects in survPen formulae

Description

Used inside a formula object to define a random effect.

Usage

```
rd(...)
```

Arguments

... Any number of covariates separated by ","

Value

```
object of class rd. smooth. spec
```

Examples

```
\# cubic regression spline of time with 10 unspecified knots + random effect at the cluster level formula.test <- \simsmf(time,df=10) + rd(cluster)
```

24 repam

repam	Applies initial reparameterization for stable evaluation of the log de-
	terminant of the penalty matrix

Description

Transforms the object from model.cons by applying the matrix reparameterization (matrix U.F). The reparameterization is reversed at convergence by inv.repam.

Usage

```
repam(build)
```

Arguments

```
build object as returned by model.cons
```

Value

build an object as returned by model.cons

X.ini initial design matrix (before reparameterization)

S.pen.ini initial penalty matrices

Examples

```
library(survPen)

# standard spline of time with 4 knots

data <- data.frame(time=seq(0,5,length=100),event=1,t0=0)

form <- ~ smf(time,knots=c(0,1,3,5))

t1 <- eval(substitute(time), data)
  t0 <- eval(substitute(t0), data)
  event <- eval(substitute(event), data)

# Setting up the model before fitting
model.c <- model.cons(form,lambda=0,data.spec=data,t1=t1,t1.name="time",
t0=rep(0,100),t0.name="t0",event=event,event.name="event",
expected=NULL,expected.name=NULL,type="overall",n.legendre=20,
cl="survPen(form,data,t1=time,event=event)",beta.ini=NULL)

# Reparameterization allows separating the parameters into unpenalized and
# penalized ones for maximum numerical stability
re.model.c <- repam(model.c)</pre>
```

smf 25

smf

Defining smooths in survPen formulae

Description

Used inside a formula object to define a smooth, a tensor product smooth or a tensor product interaction. Natural cubic regression splines (linear beyond the knots, equivalent to ns from package splines) are used as marginal bases. While tensor builds a tensor product of marginal bases including the intercepts, tint applies a tensor product of the marginal bases without their intercepts. Unlike tensor, the marginal effects of the covariates should also be present in the formula when using tint. For a conceptual difference between tensor products and tensor product interactions see Section 5.6.3 from Wood (2017)

Usage

```
smf(..., knots = NULL, df = NULL, by = NULL, same.rho = FALSE)
tensor(..., knots = NULL, df = NULL, by = NULL, same.rho = FALSE)
tint(..., knots = NULL, df = NULL, by = NULL, same.rho = FALSE)
```

Arguments

	Any number of covariates separated by ","
knots	numeric vector that specifies the knots of the splines (including boundaries); default is NULL, in which case the knots are spread through the covariate values using quantiles. Precisely, for the term " $smf(x,df=df1)$ ", the vector of knots will be: quantile(unique(x),seq(0,1,length=df1))
df	numeric value that indicates the number of knots (or degrees of freedom) desired; default is NULL. If knots and df are NULL, df will be set to 10
by	numeric or factor variable in order to define a varying coefficient smooth
same.rho	if the specified by variable is a factor, specifies whether the smoothing parameters should be the same for all levels; default is FALSE.

Value

object of class smf.smooth.spec, tensor.smooth.spec or tint.smooth.spec (see smooth.spec for details)

26 smooth.cons

Examples

```
# penalized cubic regression spline of time with 5 unspecified knots
 formula.test <- ~smf(time,df=5)</pre>
 # suppose that we want to fit a model from formula.test
 library(survPen)
 data(datCancer)
 mod.test <- survPen(~smf(fu,df=5) ,data=datCancer,t1=fu,event=dead)</pre>
 # then the knots can be retrieved like this:
 mod.test$list.smf[[1]]$knots
 # or calculated like this
 quantile(unique(datCancer$fu), seq(0,1,length=5))
 # penalized cubic regression splines of time and age with respectively 5 and 7 unspecified knots
 formula.test2 <- ~smf(time,df=5)+smf(age,df=7)</pre>
 # penalized cubic regression splines of time and age with respectively 3 and 4 specified knots
 formula.test3 <- \simsmf(time,knots=c(0,3,5))+smf(age,knots=c(30,50,70,90))
 # penalized tensor product for time and age with respectively 5 and 4 unspecified knots leading
 # to 5*4 = 20 regression parameters
 formula.test <- ~tensor(time,age,df=c(5,4))</pre>
 # penalized tensor product for time and age with respectively 3 and 4 specified knots
 formula.test3 <- \simtensor(time,agec,knots=list(c(0,3,5),c(30,50,70,90)))
 # penalized tensor product for time, age and year with respectively 6, 5 and 4 unspecified knots
 formula.test <- ~tensor(time,age,year,df=c(6,5,4))</pre>
 # penalized tensor product interaction for time and age with respectively 5 and 4 unspecified knots
 # main effects are specified as penalized cubic regression splines
 formula.test <-\infty f(time, df=5) + smf(age, df=4) + tint(time, age, df=c(5,4))
smooth.cons
                          Design and penalty matrices of penalized splines in a smooth.spec ob-
                          ject
```

Description

Builds the design and penalty matrices from the result of smooth.spec.

```
smooth.cons(
  term,
```

smooth.cons 27

```
knots,
df,
by = NULL,
option,
data.spec,
same.rho = FALSE,
name
)
```

Arguments

term Vector of strings that generally comes from the value "term" of a smooth.spec

object.

knots List of numeric vectors that specifies the knots of the splines (including bound-

aries).

df Degrees of freedom: numeric vector that indicates the number of knots desired

for each covariate.

by numeric or factor variable in order to define a varying coefficient smooth; default

is NULL.

option "smf", "tensor" or "tint".

data frame that represents the environment from which the covariate values and

knots are to be calculated; default is NULL.

same. rho if there is a factor by variable, should the smoothing parameters be the same for

all levels; default is FALSE.

name simplified name of the smooth.spec call.

Value

List of objects with the following items:

X Design matrix

pen List of penalty matrices

term Vector of strings giving the names of each covariate

knots list of numeric vectors that specifies the knots for each covariate

dim Number of covariates

all.df Numeric vector giving the number of knots associated with each covariate

sum.df Sum of all.df

Z.smf List of matrices that represents the sum-to-zero constraint to apply for "smf"

splines

Z. tensor List of matrices that represents the sum-to-zero constraint to apply for "tensor"

splines

Z.tint List of matrices that represents the sum-to-zero constraint to apply for "tint"

splines

lambda.name name of the smoothing parameters

28 smooth.cons.integral

Examples

```
library(survPen)
# standard spline of time with 4 knots (so we get a design matrix with 3 columns
# because of centering constraint)

data <- data.frame(time=seq(0,5,length=100))
smooth.c <- smooth.cons("time",knots=list(c(0,1,3,5)),df=4,option="smf",
data.spec=data,name="smf(time)")</pre>
```

smooth.cons.integral Design matrix of penalized splines in a smooth.spec object for Gauss-Legendre quadrature

Description

Almost identical to smooth.cons. This version is dedicated to Gauss-Legendre quadrature. Here, the sum-to-zero constraints must be specified so that they correspond to the ones that were calculated with the initial dataset.

Usage

```
smooth.cons.integral(
  term,
  knots,
  df,
  by = NULL,
  option,
  data.spec,
  Z.smf,
  Z.tensor,
  Z.tint,
  name
)
```

Arguments

term	Vector of strings that generally comes from the value "term" of a smooth.spec object
knots	List of numeric vectors that specifies the knots of the splines (including boundaries).
df	Degrees of freedom: numeric vector that indicates the number of knots desired for each covariate.
by	numeric or factor variable in order to define a varying coefficient smooth; default is NULL.

smooth.spec 29

option	"smf", "tensor" or "tint".
data.spec	data frame that represents the environment from which the covariate values and knots are to be calculated; default is NULL.
Z.smf	List of matrices that represents the sum-to-zero constraint to apply for smf splines.
Z.tensor	List of matrices that represents the sum-to-zero constraint to apply for tensor splines.
Z.tint	List of matrices that represents the sum-to-zero constraint to apply for tint splines.
name	simplified name of the smooth.spec call.

Value

design matrix

Examples

```
library(survPen)
# standard spline of time with 4 knots (so we get a design matrix with 3 columns
# because of centering constraint)

data <- data.frame(time=seq(0,5,length=100))

# retrieving sum-to-zero constraint matrices
Z.smf <- smooth.cons("time",knots=list(c(0,1,3,5)),df=4,option="smf",
data.spec=data,name="smf(time)")$Z.smf

# constructing the design matrices for Gauss-Legendre quadrature
smooth.c.int <- smooth.cons.integral("time",knots=list(c(0,1,3,5)),df=4,option="smf",data.spec=data,name="smf(time)",Z.smf=Z.smf,Z.tensor=NULL,Z.tint=NULL)</pre>
```

smooth.spec

Covariates specified as penalized splines

Description

Specifies the covariates to be considered as penalized splines.

```
smooth.spec(
    ...,
  knots = NULL,
  df = NULL,
```

30 smooth.spec

```
by = NULL,
option = NULL,
same.rho = FALSE
)
```

Arguments

Numeric vectors specified in smf, tensor or tint

List of numeric vectors that specifies the knots of the splines (including boundaries); default is NULL

Degrees of freedom: numeric vector that indicates the number of knots desired for each covariate; default is NULL

by numeric or factor variable in order to define a varying coefficient smooth; default is NULL

option "smf", "tensor" or "tint". Depends on the wrapper function; default is "smf" if there is a factor by variable, should the smoothing parameters be the same for

all levels; default is FALSE.

Value

object of class smooth.spec

term Vector of strings giving the names of each covariate specified in ...

Numeric value giving the number of covariates associated with this spline list of numeric vectors that specifies the knots for each covariate

Numeric vector giving the number of knots associated with each covariate numeric or factor variable in order to define a varying coefficient smooth if there is a factor by variable, should the smoothing parameters be the same for all levels; default is FALSE

simplified name of the call to function smooth.spec

Examples

```
library(survPen)

# standard spline of time with 10 unspecified knots
smooth.spec(time)

# tensor of time and age with 5*5 specified knots
smooth.s <- smooth.spec(time,age,knots=list(time=seq(0,5,length=5),age=seq(20,80,length=5)),
option="tensor")</pre>
```

summary.survPen 31

summary.survPen Summ	<i>ary for a</i> surv	Pen <i>fit</i>
----------------------	-----------------------	----------------

Description

Takes a fitted survPen object and produces various useful summaries from it.

Usage

```
## S3 method for class 'survPen'
summary(object, ...)
```

Arguments

object a fitted survPen object as produced by survPen.fit

... other arguments

Value

List of objects:

call the original survPen call formula the original survPen formula

coefficients reports the regression parameters estimates for unpenalized terms with the asso-

ciated standard errors

edf.per.smooth reports the edf associated with each smooth term random TRUE if there are random effects in the model

random.effects reports the estimates of the log standard deviation (log(sd)) of every random

effects plus the estimated standard error (also on the log(sd) scale)

likelihood unpenalized likelihood of the model

penalized.likelihood

penalized likelihood of the model

nb. smooth number of smoothing parameters

smoothing.parameter

smoothing parameters estimates

parameters number of regression parameters edf effective degrees of freedom

method smoothing selection criterion used (LAML or LCV)

val.criterion minimized value of criterion. For LAML, what is reported is the negative log

marginal likelihood

converged convergence indicator, TRUE or FALSE. TRUE if Hess.beta.modif=FALSE and

Hess.rho.modif=FALSE (or NULL)

Examples

```
library(survPen)

data(datCancer) # simulated dataset with 2000 individuals diagnosed with cervical cancer

# model : unidimensional penalized spline for time since diagnosis with 5 knots
f1 <- ~smf(fu,df=5)

# fitting hazard model
mod1 <- survPen(f1,data=datCancer,t1=fu,event=dead,expected=NULL,method="LAML")

# summary
summary(mod1)

survPen

(Excess) hazard model with (multidimensional) penalized splines and
integrated smoothness estimation
```

Description

Fits an (excess) hazard model with (multidimensional) penalized splines allowing for time-dependent effects, non-linear effects and interactions between several continuous covariates. The linear predictor is specified on the logarithm of the (excess) hazard. Smooth terms are represented using cubic regression splines with associated quadratic penalties. For multidimensional smooths, tensor product splines or tensor product interactions are available. Smoothness is estimated automatically by optimizing one of two criteria: Laplace approximate marginal likelihood (LAML) or likelihood cross-validation (LCV). When specifying the model's formula, no distinction is made between the part relative to the form of the baseline hazard and the one relative to the effects of the covariates. Thus, time-dependent effects are naturally specified as interactions with some function of time via "*" or ":". See the examples below for more details. The main functions of the survPen package are survPen, smf, tensor, tint and rd. The first one fits the model while the other four are constructors for penalized splines.

The user must be aware that the survPen package does not depend on mgcv. Thus, all the functionalities available in mgcv in terms of types of splines (such as thin plate regression splines or P-splines) are not available in survPen (yet).

```
survPen(
  formula,
  data,
  t1,
  t0 = NULL,
  event,
  expected = NULL,
```

```
lambda = NULL,
rho.ini = NULL,
max.it.beta = 200,
max.it.rho = 30,
beta.ini = NULL,
detail.rho = FALSE,
detail.beta = FALSE,
n.legendre = 20,
method = "LAML",
tol.beta = 1e-04,
tol.rho = 1e-04,
step.max = 5
```

Arguments

8	
formula	formula object specifying the model. Penalized terms are specified using smf (comparable to s(,bs="cr") in mgcv), tensor (comparable to te(,bs="cr") in mgcv), tint (comparable to ti(,bs="cr") in mgcv), or rd (comparable to s(,bs="re") in mgcv).
data	an optional data frame containing the variables in the model
t1	vector of follow-up times or name of the column in data containing follow-up times
t0	vector of origin times or name of the column in data containing origin times; allows to take into account left truncation; default is NULL, in which case it will be a vector of zeroes
event	vector of right-censoring indicators or name of the column in data containing right-censoring indicators; 1 if the event occurred and 0 otherwise
expected	(for net survival only) vector of expected hazard or name of the column in data containing expected hazard; default is NULL, in which case overall survival will be estimated
lambda	vector of smoothing parameters; default is NULL when it is to be estimated by LAML or LCV
rho.ini	vector of initial log smoothing parameters; default is NULL, in which case every initial log lambda will be -1
max.it.beta	maximum number of iterations to reach convergence in the regression parameters; default is 200
max.it.rho	maximum number of iterations to reach convergence in the smoothing parameters; default is 30
beta.ini	vector of initial regression parameters; default is NULL, in which case the first beta will be log(sum(event)/sum(t1)) and the others will be zero (except if there are "by" variables in which case all betas are set to zero)
detail.rho	if TRUE, details concerning the optimization process in the smoothing parameters are displayed; default is FALSE
detail.beta	if TRUE, details concerning the optimization process in the regression parameters are displayed; default is FALSE

n.legendre	number of Gauss-Legendre quadrature nodes to be used to compute the cumulative hazard; default is 20
method	criterion used to select the smoothing parameters. Should be "LAML" or "LCV"; default is "LAML" $$
tol.beta	convergence tolerance for regression parameters; default is $1e-04$. See NR. beta for details
tol.rho	convergence tolerance for smoothing parameters; default is 1e-04. See NR.rho for details
step.max	maximum absolute value possible for any component of the step vector (on the log smoothing parameter scale) in LCV or LAML optimization; default is 5. If necessary, consider lowering this value to achieve convergence

Details

In time-to-event analysis, we may deal with one or several continuous covariates whose functional forms, time-dependent effects and interaction structure are challenging. One possible way to deal with these effects and interactions is to use the classical approximation of the survival likelihood by a Poisson likelihood. Thus, by artificially splitting the data, the package mgcv can then be used to fit penalized hazard models (Remontet et al. 2018). The problem with this option is that the setup is rather complex and the method can fail with huge datasets (before splitting). Wood et al. (2016) provided a general penalized framework that made available smooth function estimation to a wide variety of models. They proposed to estimate smoothing parameters by maximizing a Laplace approximate marginal likelihood (LAML) criterion and demonstrate how statistical consistency is maintained by doing so. The survPen function implements the framework described by Wood et al. (2016) for modelling time-to-event data without requiring data splitting and Poisson likelihood approximation. The effects of continuous covariates are represented using low rank spline bases with associated quadratic penalties. The survPen function allows to account simultaneously for time-dependent effects, non-linear effects and interactions between several continuous covariates without the need to build a possibly demanding model-selection procedure. Besides LAML, a likelihood cross-validation (LCV) criterion (O Sullivan 1988) can be used for smoothing parameter estimation. First and second derivatives of LCV with respect to the smoothing parameters are implemented so that LCV optimization is computationally equivalent to the LAML optimization proposed by Wood et al. (2016). In practice, LAML optimization is generally both a bit faster and a bit more stable so it is used as default. For m covariates (x_1,\ldots,x_m) , if we note $h(t,x_1,\ldots,x_m)$ the hazard at time t, the hazard model is the following:

$$log[h(t, x_1, \dots, x_m)] = \sum_j g_j(t, x_1, \dots, x_m)$$

where each g_j is either the marginal basis of a specific covariate or a tensor product smooth of any number of covariates. The marginal bases of the covariates are represented as natural (or restricted) cubic splines (as in function ns from library splines) with associated quadratic penalties. Full parametric (unpenalized) terms for the effects of covariates are also possible (see the examples below). Each g_j is then associated with zero, one or several smoothing parameters. The estimation procedure is based on outer Newton-Raphson iterations for the smoothing parameters and on inner Newton-Raphson iterations for the regression parameters (see Wood et al. 2016). Estimation of the regression parameters in the inner algorithm is by direct maximization of the penalized likelihood of the survival model, therefore avoiding data augmentation and Poisson likelihood approximation.

The cumulative hazard included in the log-likelihood is approximated by Gauss-Legendre quadrature for numerical stability.

Value

Object of class "survPen" (see survPenObject for details)

by variables

The smf, tensor and tint terms used to specify smooths accept an argument by. This by argument allows for building varying-coefficient models i.e. for letting smooths interact with factors or parametric terms. If a by variable is numeric, then its ith element multiples the ith row of the model matrix corresponding to the smooth term concerned. If a by variable is a factor then it generates an indicator vector for each level of the factor, unless it is an ordered factor. In the non-ordered case, the model matrix for the smooth term is then replicated for each factor level, and each copy has its rows multiplied by the corresponding rows of its indicator variable. The smoothness penalties are also duplicated for each factor level. In short a different smooth is generated for each factor level. The main interest of by variables over separated models is the same rho argument (for smf, tensor and tint) which allows forcing all smooths to have the same smoothing parameter(s). Ordered by variables are handled in the same way, except that no smooth is generated for the first level of the ordered factor. This is useful if you are interested in differences from a reference level.

See the survival_analysis_with_survPen vignette for more details.

Random effects

i.i.d random effects can be specified using penalization. Indeed, the ridge penalty is equivalent to an assumption that the regression parameters are i.i.d. normal random effects. Thus, it is easy to fit a frailty hazard model. For example, consider the model term rd(clust) which will result in a model matrix component corresponding to model.matrix(~clust-1) being added to the model matrix for the whole model. The associated regression parameters are assumed i.i.d. normal, with unknown variance (to be estimated). This assumption is equivalent to an identity penalty matrix (i.e. a ridge penalty) on the regression parameters. The unknown smoothing parameter λ associated with the term rd(clust) is directly linked to the unknown variance σ^2 : $\sigma^2 = \frac{1}{\lambda * S. scale}$. Then, the estimated log standard deviation is: $log(\hat{\sigma}) = -0.5 * log(\hat{\lambda}) - 0.5 * log(S.scale)$. And the estimated variance of the log standard deviation is: $Var[log(\hat{\sigma})] = 0.25 * Var[log(\hat{\lambda})] = 0.25 * inv.Hess.rho$. See the survival_analysis_with_survPen vignette for more details. This approach allows implementing commonly used random effect structures. For example if g is a factor then rd(g) produces a random parameter for each level of g, the random parameters being i.i.d. normal. If g is a factor and x is numeric, then rd(g,x) produces an i.i.d. normal random slope relating the response to x for each level of g. Thus, random effects treated as penalized splines allow specifying frailty (excess) hazard models (Charvat et al. 2016). For each individual i from cluster (usually geographical unit) j, a possible model would be:

$$log[h(t_{ij}, x_{ij1}, \dots, x_{ijm})] = \sum_{k} g_k(t_{ij}, x_{ij1}, \dots, x_{ijm}) + w_j$$

where w_j follows a normal distribution with mean 0. The random effect associated with the cluster variable is specified with the model term rd(cluster). We could also specify a random effect

depending on age for example with the model term rd(cluster, age). $u_j = exp(w_j)$ is known as the shared frailty.

See the survival_analysis_with_survPen vignette for more details.

Excess hazard model

When studying the survival of patients who suffer from a common pathology we may be interested in the concept of excess mortality that represents the mortality due to that pathology. For example, in cancer epidemiology, individuals may die from cancer or from another cause. The problem is that the cause of death is often either unavailable or unreliable. Supposing that the mortality due to other causes may be obtained from the total mortality of the general population (called expected mortality for cancer patients), we can define the concept of excess mortality. The excess mortality is directly linked to the concept of net survival, which would be the observed survival if patients could not die from other causes. Therefore, when such competing events are present, one may choose to fit an excess hazard model instead of a classical hazard model. Flexible excess hazard models have already been proposed (for examples see Remontet et al. 2007, Charvat et al. 2016) but none of them deals with a penalized framework (in a non-fully Bayesian setting). Excess mortality can be estimated supposing that, in patients suffering from a common pathology, mortality due to others causes than the pathology can be obtained from the (all cause) mortality of the general population; the latter is referred to as the expected mortality h_P . The mortality observed in the patients (h_O) is actually decomposed as the sum of h_P and the excess mortality due to the pathology (h_E) . This may be written as:

$$h_O(t, x) = h_E(t, x) + h_P(a + t, z)$$

In that equation, t is the time since cancer diagnosis, a is the age at diagnosis, h_P is the mortality of the general population at age a+t given demographical characteristics z (h_P is considered known and available from national statistics), and x a vector of variables that may have an effect on h_E . Including the age in the model is necessary in order to deal with the informative censoring due to other causes of death. Thus, for m covariates (x_1, \ldots, x_m) , if we note $h_E(t, x_1, \ldots, x_m)$ the excess hazard at time t, the excess hazard model is the following:

$$log[h_E(t, x_1, \dots, x_m)] = \sum_j g_j(t, x_1, \dots, x_m)$$

Convergence

No convergence indicator is given. If the function returns an object of class survPen, it means that the algorithm has converged. If convergence issues occur, an error message is displayed. If convergence issues occur, do not refrain to use detail.rho and/or detail.beta to see exactly what is going on in the optimization process. To achieve convergence, consider lowering step.max and/or changing rho.ini and beta.ini. If your excess hazard model fails to converge, consider fitting a hazard model and use its estimated parameters as initial values for the excess hazard model. Finally, do not refrain to change the "method" argument (LCV or LAML) if convergence issues occur.

Other

Be aware that all character variables are transformed to factors before fitting.

survPen.fit (Excess) hazard model with multidimensional penalized splines for given smoothing parameters

Description

Fits an (excess) hazard model. If penalized splines are present, the smoothing parameters are specified.

Usage

```
survPen.fit(
  build,
  data,
  formula,
  max.it.beta = 200,
  beta.ini = NULL,
  detail.beta = FALSE,
  method = "LAML",
  tol.beta = 1e-04
)
```

Arguments

build	list of objects returned by model.cons
data	an optional data frame containing the variables in the model
formula	formula object specifying the model
max.it.beta	maximum number of iterations to reach convergence in the regression parameters; default is 200
beta.ini	vector of initial regression parameters; default is NULL, in which case the first beta will be log(sum(event)/sum(t1)) and the others will be zero (except if there are "by" variables in which case all betas are set to zero)
detail.beta	if TRUE, details concerning the optimization process in the regression parameters are displayed; default is FALSE
method	criterion used to select the smoothing parameters. Should be "LAML" or "LCV"; default is "LAML" $$
tol.beta	convergence tolerance for regression parameters; default is $1e-04$. See NR. beta for details

44 survPenObject

Value

Object of class "survPen" (see survPenObject for details)

Examples

```
library(survPen)

# standard spline of time with 4 knots

data <- data.frame(time=seq(0,5,length=100),event=1,t0=0)

form <- ~ smf(time,knots=c(0,1,3,5))

t1 <- eval(substitute(time), data)
 t0 <- eval(substitute(t0), data)
 event <- eval(substitute(event), data)

# Setting up the model before fitting
model.c <- model.cons(form,lambda=0,data.spec=data,t1=t1,t1.name="time",
t0=rep(0,100),t0.name="t0",event=event.name="event",
expected=NULL,expected.name=NULL,type="overall",n.legendre=20,
cl="survPen(form,data,t1=time,event=event)",beta.ini=NULL)

# fitting
mod <- survPen.fit(model.c,data,form)</pre>
```

survPenObject

Fitted survPen object

Description

A fitted survPen object returned by function survPen and of class "survPen". Method functions predict and summary are available for this class.

Value

A survPen object has the following elements:

call	original survPen call
formula	formula object specifying the model
t0.name	name of the vector of origin times
t1.name	name of the vector of follow-up times
event.name	name of the vector of right-censoring indicators
expected.name	name of the vector of expected hazard
haz	fitted hazard

survPenObject 45

coefficients	estimated regression parameters. Unpenalized parameters are first, followed by the penalized ones		
type	"net" for net survival estimation with penalized excess hazard model or "overall" for overall survival with penalized hazard model		
df.para	degrees of freedom associated with fully parametric terms (unpenalized)		
df.smooth	degrees of freedom associated with penalized terms		
р	number of regression parameters		
edf	effective degrees of freedom		
edf1	alternative effective degrees of freedom; used as an upper bound for edf2		
edf2	effective degrees of freedom corrected for smoothing parameter uncertainty		
aic	Akaike information criterion with number of parameters replaced by edf when there are penalized terms. Corresponds to 2*edf - 2*ll.unpen		
aic2	Akaike information criterion corrected for smoothing parameter uncertainty. Be careful though, this is still a work in progress, especially when one of the smoothing parameters tends to infinity.		
iter.beta	vector of numbers of iterations needed to estimate the regression parameters for each smoothing parameters trial. It thus contains iter.rho+1 elements.		
Χ	design matrix of the model		
S	penalty matrix of the model		
S.scale	vector of rescaling factors for the penalty matrices		
S.list	Equivalent to pen but with every element multiplied by its associated smoothing parameter		
S.smf	List of penalty matrices associated with all "smf" calls		
S.tensor	List of penalty matrices associated with all "tensor" calls		
S.tint	List of penalty matrices associated with all "tint" calls		
S.rd	List of penalty matrices associated with all "rd" calls		
smooth.name.smf			
List of names for the "smf" calls associated with S.smf			
Sillootii. Hallic . ter	List of names for the "tensor" calls associated with S.tensor		
smooth.name.tir			
	List of names for the "tint" calls associated with S.tint		
smooth.name.rd	List of names for the "rd" calls associated with S.rd		
S.pen	List of all the rescaled penalty matrices redimensioned to df.tot size. Every element of S.pen noted S.pen[[i]] is made from a penalty matrix pen[[i]] returned by smooth.cons and is multiplied by S.scale		
grad.unpen.beta			
	gradient vector of the log-likelihood with respect to the regression parameters		
grad.beta	gradient vector of the penalized log-likelihood with respect to the regression parameters		
Hess . unpen . beta			
	hessian of the log-likelihood with respect to the regression parameters		

46 survPenObject

Hess.beta hessian of the penalized log-likelihood with respect to the regression parameters Hess.beta.modif

if TRUE, the hessian of the penalized log-likelihood has been perturbed at con-

vergence

11. unpen log-likelihood at convergence

11. pen penalized log-likelihood at convergence

deriv.rho.beta transpose of the Jacobian of beta with respect to the log smoothing parameters

deriv.rho.inv.Hess.beta

list containing the derivatives of the inverse of Hess with respect to the log

smoothing parameters

deriv.rho.Hess.unpen.beta

list containing the derivatives of Hess. unpen with respect to the log smoothing

parameters

lambda estimated or given smoothing parameters

nb. smooth number of smoothing parameters

iter.rho number of iterations needed to estimate the smoothing parameters

optim.rho identify whether the smoothing parameters were estimated or not; 1 when exit-

ing the function NR. rho; default is NULL

method criterion used for smoothing parameter estimation

criterion.val value of the criterion used for smoothing parameter estimation at convergence

LCV Likelihood cross-validation criterion at convergence

LAML negative Laplace approximate marginal likelihood at convergence

grad.rho gradient vector of criterion with respect to the log smoothing parameters

Hess.rho hessian matrix of criterion with respect to the log smoothing parameters

inv.Hess.rho inverse of Hess.rho

Hess.rho.modif if TRUE, the hessian of LCV or LAML has been perturbed at convergence

Ve Frequentist covariance matrix
Vp Bayesian covariance matrix

Vc Bayesian covariance matrix corrected for smoothing parameter uncertainty (see

Wood et al. 2016)

Vc. approx Kass and Steffey approximation of Vc (see Wood et al. 2016)

Z.smf List of matrices that represents the sum-to-zero constraint to apply for smf

splines

Z. tensor List of matrices that represents the sum-to-zero constraint to apply for tensor

splines

Z.tint List of matrices that represents the sum-to-zero constraint to apply for tint

splines

list.smf List of all smf.smooth.spec objects contained in the model
list.tensor List of all tensor.smooth.spec objects contained in the model
list.tint List of all tint.smooth.spec objects contained in the model

tensor.in 47

list.rd List of all rd. smooth. spec objects contained in the model

U.F Eigen vectors of S.F, useful for the initial reparameterization to separate penal-

ized ad unpenalized subvectors. Allows stable evaluation of the log determinant

of S and its derivatives

factor.structure

List containing the levels and classes of all factor variables present in the data

frame used for fitting

converged convergence indicator, TRUE or FALSE. TRUE if Hess.beta.modif=FALSE and

Hess.rho.modif=FALSE (or NULL)

tensor.in

tensor model matrix for two marginal bases

Description

Function called recursively inside tensor.prod.X.

Usage

```
tensor.in(X1, X2)
```

Arguments

X1 first marginal design matrix with n rows and p1 columns
 X2 first marginal design matrix with n rows and p2 columns

Value

Matrix of dimensions n*(p1*p2) representing the row tensor product of the matrices X1 and X2

Examples

```
library(survPen)
# row-wise tensor product between two design matrices
set.seed(15)

X1 <- matrix(rnorm(10*3),nrow=10,ncol=3)
X2 <- matrix(rnorm(10*2),nrow=10,ncol=2)
tensor.in(X1,X2)</pre>
```

48 tensor.prod.X

tensor.prod.S

Tensor product for penalty matrices

Description

Computes the penalty matrices of a tensor product smooth from the marginal penalty matrices. The code is from function tensor.prod.penalties in mgcv package.

Usage

```
tensor.prod.S(S)
```

Arguments

S

list of m marginal penalty matrices

Value

TS

List of the penalty matrices associated with the tensor product smooth

Examples

```
library(survPen)
# tensor product between three penalty matrices
set.seed(15)

S1 <- matrix(rnorm(3*3),nrow=3,ncol=3)
S2 <- matrix(rnorm(2*2),nrow=2,ncol=2)

S1 <- 0.5*(S1 + t(S1) ) ; S2 <- 0.5*(S2 + t(S2) )
tensor.prod.S(list(S1,S2))</pre>
```

tensor.prod.X

tensor model matrix

Description

Computes the model matrix of tensor product smooth from the marginal bases.

Usage

```
tensor.prod.X(X)
```

%cross% 49

Arguments

X list of m design matrices with n rows and p1, p2, ... pm columns respectively

Value

T Matrix of dimensions n*(p1*p2*...*pm) representing the row tensor product of the matrices in X

Examples

```
library(survPen)
# row-wise tensor product between three design matrices
set.seed(15)

X1 <- matrix(rnorm(10*3),nrow=10,ncol=3)
X2 <- matrix(rnorm(10*2),nrow=10,ncol=2)
X3 <- matrix(rnorm(10*2),nrow=10,ncol=2)
tensor.prod.X(list(X1,X2,X3))</pre>
```

%cross%

Matrix cross-multiplication between two matrices

Description

Matrix cross-multiplication between two matrices

Usage

```
Mat1 %cross% Mat2
```

Arguments

Mat1 a matrix.

Mat2 another matrix.

Value

```
prod the product t(Mat1)
```

50 %vec%

%mult%

Matrix multiplication between two matrices

Description

Matrix multiplication between two matrices

Usage

Mat1 %mult% Mat2

Arguments

Mat1 a matrix.

Mat2 another matrix.

Value

prod the product Mat1

%vec%

Matrix multiplication between a matrix and a vector

Description

Matrix multiplication between a matrix and a vector

Usage

Mat %vec% vec

Arguments

Mat a matrix. vec a vector.

Value

prod the product Mat
